DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

The New Canadian-Detroit Double-D Rolled Drill

Made in Canada

PRODUCTION requirements in an ever-increasing number of plants necessitate the use of a strong, accurate drill, specially designed for hard drop forgings, steel castings, and other alloy steels equally tough and difficult to drill.

For this service we have developed a hot rolled process drill known as the Canadian-Detroit Double-D (DD) Rolled Drill. It combines the strength of the forged type drill with the accuracy and uniformity of the milled type.

The flute of the DD is formed straight from the bar stock by successive passes through specially built and patented rolls at a temperature of 1850° F. This mechanical rolling of the flutes produces a refinement and uniformity in the grain of the steel and gives additional density at the centre and at the outer edge. Each drill is rolled separately, and the rolls are so designed and operated as to produce the same uniform increase in web thickness as is obtained in high-grade drill of the milled type.

The fluted drill is reheated and twisted in a specially designed automatic machine. The twisting process is held absolutely uniform, giving the same increase in helix angle from shank to point, 27° to 32°: This standard has been adopted on our milled drills and has been proven by exhaustive experiments to be the most efficient.

The DD has increased production and cut drilling costs in many of the finest plants in Canada. A fair test will convince you.

Manufactured and carried in stock at Walkerville in all sizes from ½ inch to 1½ inches.

We also manufacture and carry in stock all sizes and types of high speed and carbon milled drills.

CANADIAN-DETROIT TWIST DRILL COMPANY, LIMITED

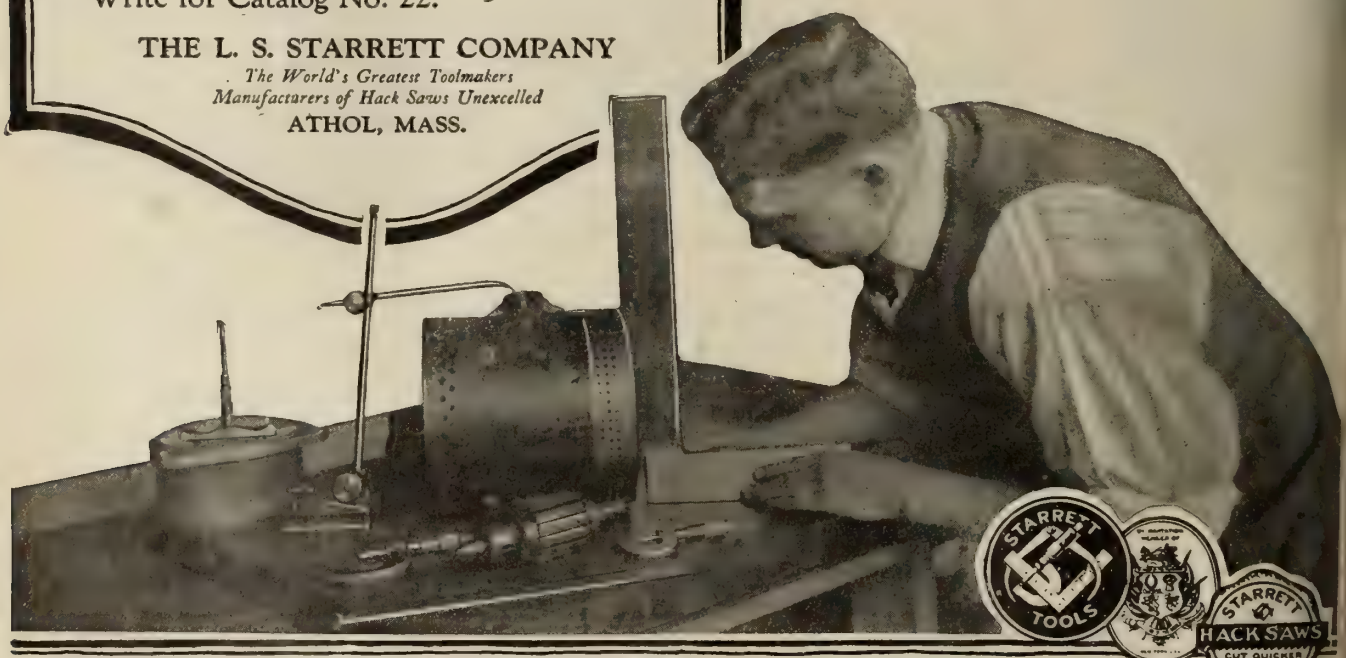
Walkerville, Ontario

Is Your Tool-Kit Equipped for this Job?

A Starrett Micrometer Depth Gage, Universal Surface Gage, Solid Steel Square, One-Inch Micrometer, and a Two-Inch Micrometer.

Suppose the Van Dorn Electric Tool Company, of Cleveland, Ohio, turned over to *you* one of these tool housings to be finished up and checked.

Could you handle the job? Have you the Starrett Tools needed—tools such as the inspector is using in the illustration below?



Make sure your kit is fully equipped with Starrett Tools.

SMALL TOOLS

Pratt & Whitney Adjustable Blade Reamers

These reamers have eccentric relief and can be set to size without regrinding. They are unexcelled for design and simplicity and ease of adjustment.

The eccentrically relieved blades are stronger than others, do not chatter, and produce a smoother hole. The hand, shell and fluted chucking reamers have interchangeable nuts, screws and wrenches. The bottom of a hole can readily be faced.

By a simple adjustment of the blades the reamer can easily be set to size, without regrinding.

Prompt service is assured at our nearest store, where P. & W. Small Tools are carried in stock for immediate delivery. Place your order there to-day.

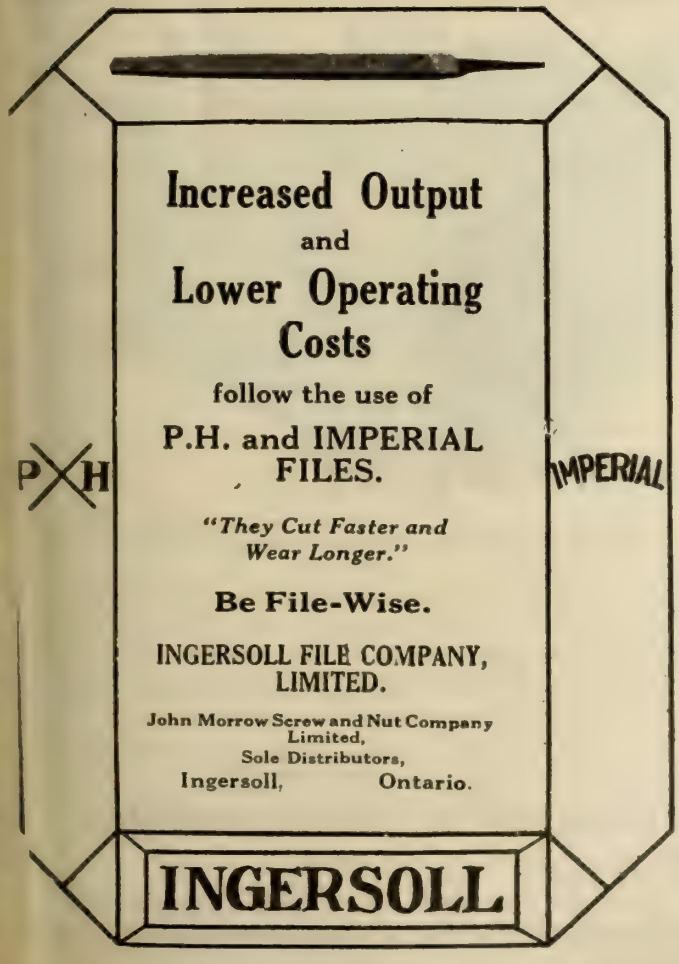
How to Plant an Advertising Crop

Until the advent of the Audit Bureau of Circulations, advertisers sowed their business seed in a vast but fallow field. Some of it grew and returned a fair harvest—much of it was cast upon barren ground and was lost. There was no standardized method of determining the fertility of a publication's field. Experimenting was expensive.

The A. B. C. has eliminated the barren spots of circulation. Planting an advertising crop is no longer an experiment. Advertisers **Know** the field through audit reports. They know whether it is fertile ground and sow their seed accordingly.



The Canadian Machinery circulation has been audited by the A. B. C. Advertisements placed in this publication are seeds well sown.

THE JOHNSON FRICTION CLUTCH

It's a Johnson Lineshaft Drive

A battery of twelve light presses, all on a bench about 30 x 5, driven from one lineshaft with Johnson Clutches controlling the machines.

COMPARE IT FOR FIRST COST

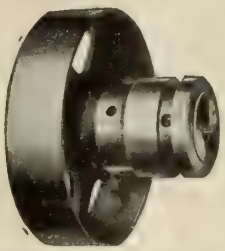
Twelve Clutches against twelve complete counter shafts, or twelve individual motors.

COMPARE IT FOR EFFICIENCY.

Quick, smooth control against the sluggish tight and loose pulley. Or one motor consuming current instead of twelve.

COMPARE IT FOR SERVICE.

You know the failing of belts—the continual attention they require, especially when they are shifted. If you don't know Johnson Clutch Service, just give it a trial.



Write for our booklet

"Clutches As Applied to Machine Building." and our Yellow Catalog.

Illustration by courtesy of The New Departure Manufacturing Co., showing bench presses in operation at their Elmwood Plant.

FRICTION CONTROL MEANS BETTER MACHINERY

We specialize in applying the proper type of friction clutch on any sort of an installation. Standard clutches available from stock, and special models developed to suit conditions.

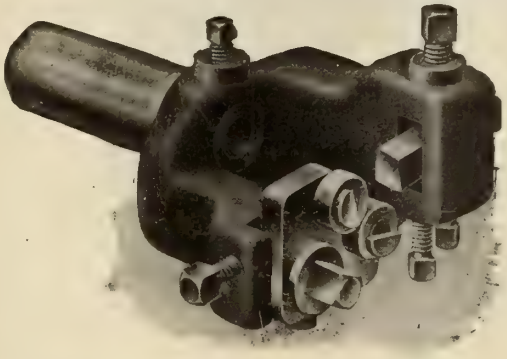
Bowser 6F Oil Filtering and Circulating System

When Clean Oil Flows Freely

Bowser Oil Filtering and Circulating Systems keep the clean oil flowing onto the bearings in a constant stream—insure efficient lubrication always.

At the same time Bowser Filtering Systems keep the oil bill down. They collect the used oil and filter it, making it ready for re-use—give several gallons of good clean oil for the price of one.

There is also a great reduction in labor. The Bowser System is so nearly automatic, it requires practically no attention.



It will pay you to investigate.

WRITE US TODAY FOR LITERATURE.

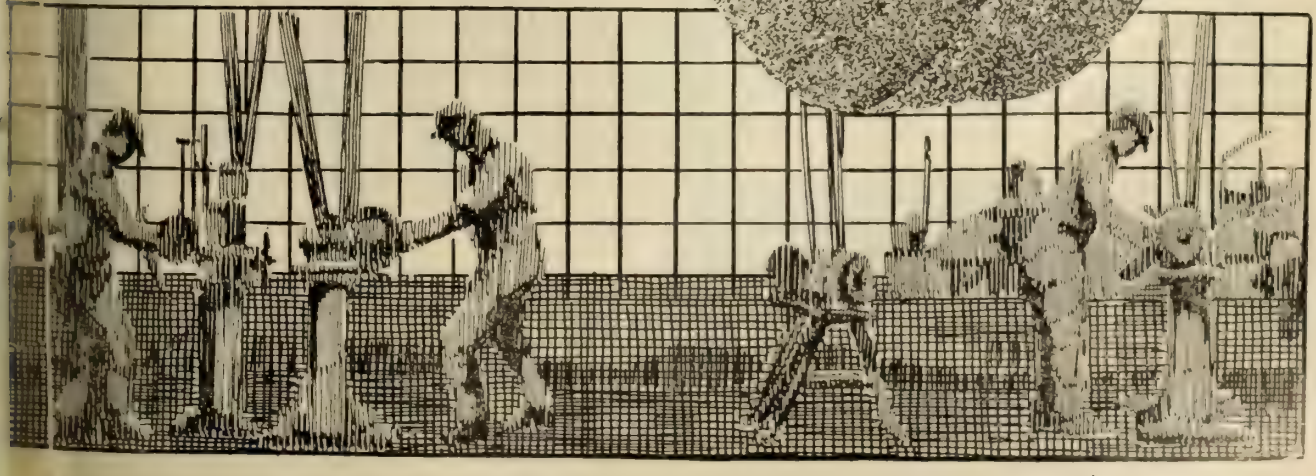
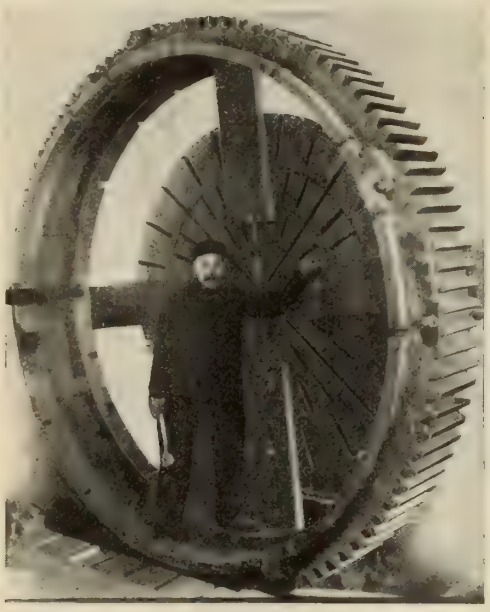
CANADIAN HART GRINDING WHEELS



THE factory tests that all Canadian Hart Wheels are subjected to gives you an absolute guarantee that they are free from defects. Each wheel is also carefully inspected for size, grain and grade, so as to make certain that every wheel is in accordance with specifications on your order.

Canadian Hart Wheels are not inclined to "gum up" or "glaze," because they are made of proper abrasive grains of a suitable degree of hardness; especially is this true when the buyer secures the co-operation and advice of our engineering staff with a view of getting the right wheel for the job.



How can we serve you?

Franklin Die-Castings for Musical Instruments

Spreading a Great Educational Influence.

NOT so long ago good music was a treasure of the chosen few. Years of study were necessary to play an instrument. Today, irrespective of technical skill, the great educational influence of good music is at the command of everyone. Among other modern manufacturing methods the Die-Casting Process has been instrumental in enabling the general public to enjoy good music. Franklin Die-Castings, used in phonographs, player pianos and organs, have helped to reduce production costs in the manufacture of these instruments.

Franklin engineers, in 1892, originated the die-casting process. Franklin Die-Castings have helped manufacturers ever since to speed and simplify production in many fields of industry.

The addition of the standard No. 12 Aluminum to the Tin, Lead and Zinc base alloys already in use enables us to meet a still wider range of individual needs.

We quote from samples or blueprints. Write for booklet "Franklin Die-Castings in Many Fields."

MANUFACTURING NEWS

Volume XXVI, No. 6. August 18, 1921.

The Efficiency of Industrial Furnaces

Increase in Efficiency Due to Modern Design—High Cost of Fuel is Largely Responsible for Present Eagerness to Make Furnaces as Economical as Possible.

*By HUGH CHAMBERS

HIGH COST of fuels used in industrial furnaces during the past few years has resulted in considable study of the problem of increasg the thermal efficiency of furnaces. hen it is realized that a great many dustrial heating furnaces in use in ants to-day have a thermal efficiency 10 per cent. or less, the wonderful ssibilities along these lines can be apeciated.

A comparison between a forge furnace d a steam boiler will show the reader y the ordinary furnace has such a low ficiency. Fig. 1 shows a typical steam iler in which the temperature in the febox is 2500°F. It will be noted that e temperature of the gases resulting om combustion gradually decreases un- a temperature of 520° is reached, en the gases leave the heating surface the boiler. All heat contained in the ses after they leave the heating surfe of the boiler is lost.

For purposes of comparison it may assumed that the amount of heat contained in the gases varies in direct proportion with their temperature as the weight of gases passing through a furnace or boiler remains constant and the specific heat of the gases is practically constant.

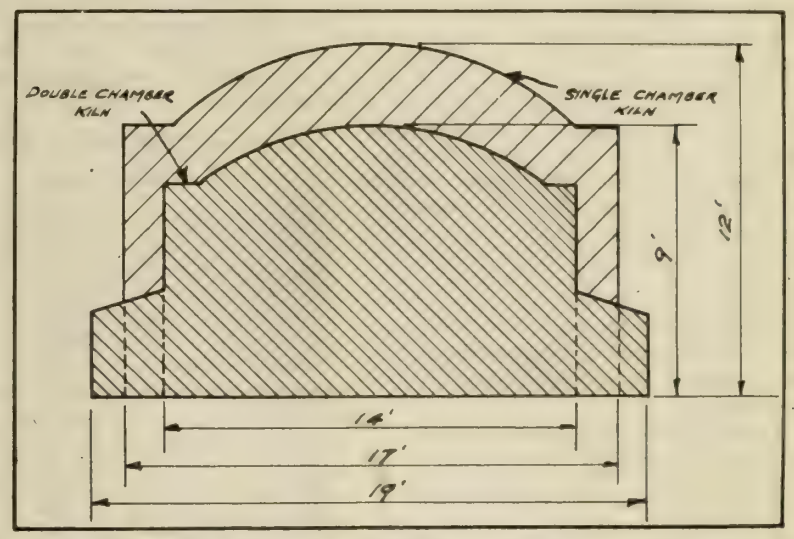

Fig. 5.—Section elevation showing relative size of single and double chamber kilns for a given output.

$$\text{Thermal efficiency of boiler} = \frac{\text{heat utilized}}{\text{heat supplied}} = \frac{\text{heat supplied} - \text{heat wasted}}{\text{heat supplied}}.$$

As the heat content of the gasses is in direct proportion to the gas temperature we have:

$$\text{Thermal efficiency of boiler} = \frac{\text{heat supplied} - \text{heat wasted}}{\text{heat supplied}} = \frac{2500 - 520}{2500} = .79 \text{ or } 79\%.$$

Fig. 2 shows diagrammatically a common type of furnace in which steel is heated to a temperature of 2200°F. for forging or rolling. The furnace gases reach a temperature of 2500°F and leave the furnace at a temperature about 100° lower than that to which the steel is being heated, or 2100°F. As the gases leave the furnace at 2100° all the heat which they contain at this temperature is wasted.

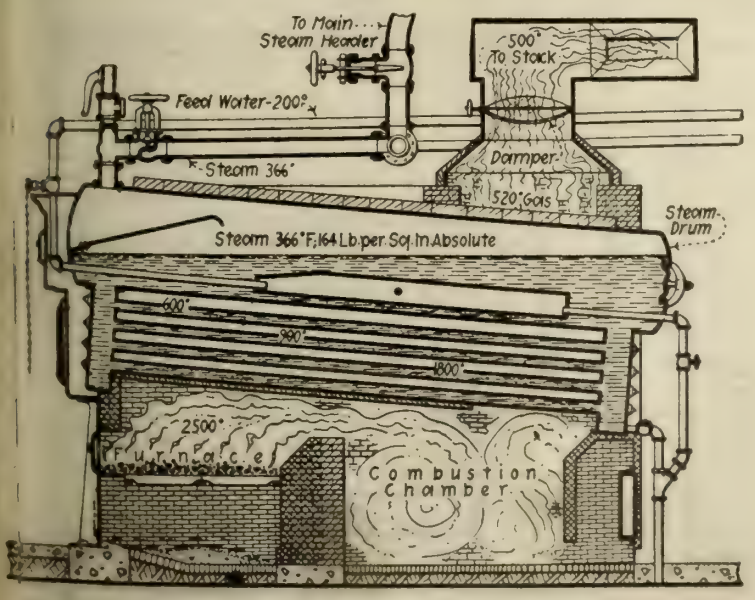

Fig. 1.—Section of a water tube boiler.

*Chief Engineer of the General Combustion Company of Canada, Ltd.

$$\text{Thermal efficiency of furnace} = \frac{\text{heat supplied} - \text{heat wasted}}{\text{heat supplied}} = \frac{2500 - 2100}{2500} = .16 \text{ or } 16\%.$$

Thus it is seen that in the case of the steam boiler it is possible to impart to the water 79% of the heat supplied in the fuel, whereas only 16% of the heat is utilized in heating the steel in the ordinary forging furnace. This great difference in efficiency is due to the fact that in one case water is heated to only 366°F., making possible a great drop in temperature of the gases, as against a small drop in temperature of the gases where steel is heated to a high temperature.

The above comparison does not account for the heat lost by radiation through the walls of the boiler setting or furnace. Had the radiation losses been taken into account, the furnace would show up still more unfavorably as compared with the boiler, as radiation losses are generally greater in furnaces than in boiler settings. Combustion of any fuel consists essentially in increasing the temperature of a given weight of air from that at which it enters the combustion chamber to whatever temperature is attained after combustion is complete. A chemical change takes place in which the oxygen of the air is replaced by an equivalent weight of CO_2. Let us consider what happens when 1 lb. of carbon is burned using cold air for combustion.

Equating the products before and after combustion theoretically, we have—

1 lb. carbon + 11.5 lbs. air) at 60°F. = 12.5lbs. furnace gases at 4915°F.

It may be noted that the temperature of the furnace gases as above indicated is not obtainable. In ordinary furnace work with coal which has approximately 85% of the B.T.U. of carbon the temperature obtainable in furnace or boilers is under ordinary conditions about ½ of the theoretical, or about 2500°.

The losses in temperature are due to—

1. Imperfect combustion.
2. Excess air.
3. Radiation.
4. Absorption of heat by the furnace and the materials heated.

Next, let us consider the theoretical combustion of fuel oil.

(1 lb. fuel oil + 14 lb. air) at 60°F. = 15 lb. furnace gases at 5420°F.

For the reasons as given above it is not possible to actually obtain temperatures higher than about 3000°F when burning fuel oil in furnaces using cold air for combustion. Since combustion is essentially a problem of heating air it follows that in order to attain a given temperature in a furnace the higher the temperature of the initial air for combustion the less fuel there will be consumed. Advantage of this fact is taken in the design of modern furnaces where the enormous amount of heat which was formerly wasted in the gases leaving the furnace is now used to preheat the incoming air for combustion of the fuel.

Effect of Recuperation on Thermal Efficiency.

Fig. 3 shows a diagram of a modern recuperative type of furnace in which the waste gases leaving the furnace are used to preheat the combustion air. Assume similar conditions to those obtaining in the furnace shown in figure 2, where the steel is heated to 2200°F. and the furnace gases attain a temperature of 2500°F. As before, the gases will leave the furnace and enter the recuperator at 2100°F. Cold air for combustion enters the recuperator at ordinary room temperature of 60° and is preheated to 800°F. while the temperature of the waste gases is reduced frbm 2100° to 1300° while passing through the recuperator.

As all the heat represented by the drop in temperature of the waste gases from 2100° to 1300° has been returned to the furnace.

$$\text{Thermal efficiency} = \frac{\text{heat supplied} - \text{heat wasted}}{\text{heat supplied}} = \frac{2500 - 1300}{2500} = .48 \text{ or } 48\%.$$

This efficiency of 48 per cent. is comparable with the efficiency of 16 per cent. obtained in a furnace working under similar conditions without recuperation. Furnaces of the recuperative type are in operation to-day showing thermal efficiencies as high as 60 per cent.

The heat loss through furnace walls is a considerable percentage of the total heat supplied in many types of industrial furnaces.

The amount of heat which is transmitted through a furnace wall varies directly as to time, surface area of wall, coefficient of heat transmission of wall material, and temperature difference between inside and outside of wall and inversely as to the wall thickness. This may be expressed in a formula as follows:

$$\text{B. T. U. transmitted through wall per hour} = \frac{A \times F \times (T_1 - T_2)}{B}$$

A = area of wall in square feet.
B = wall thickness in inches.
F = factor for wall material = 7 for firebrick.
T^1 = Temperature of inside of wall
T_2 = Temperature of outside of wall

Consider the case of two furnaces having similar chamber dimensions, one furnace, however, having a 9 in. wall of ordinary firebrick, while the other has a 13½ in. wall consisting of 9 in. firebrick plus 4½ in. of high heat insulating material having qualities which resist heat transmission 8 times that of firebrick. The heat loss per hour through each square foot of 9 in. firebrick wall assuming inside and outside wall temperatures of 2500° and 100° respectively will be:

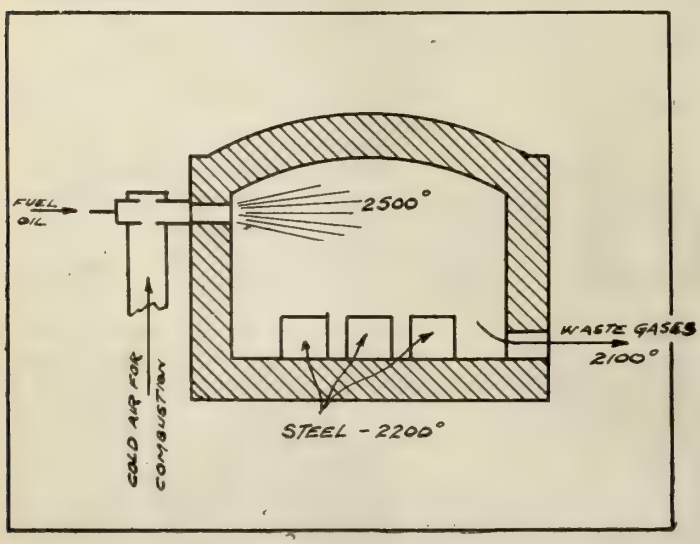

Fig. 2.—Diagram showing common type of forging furnace using cold air for combustion.

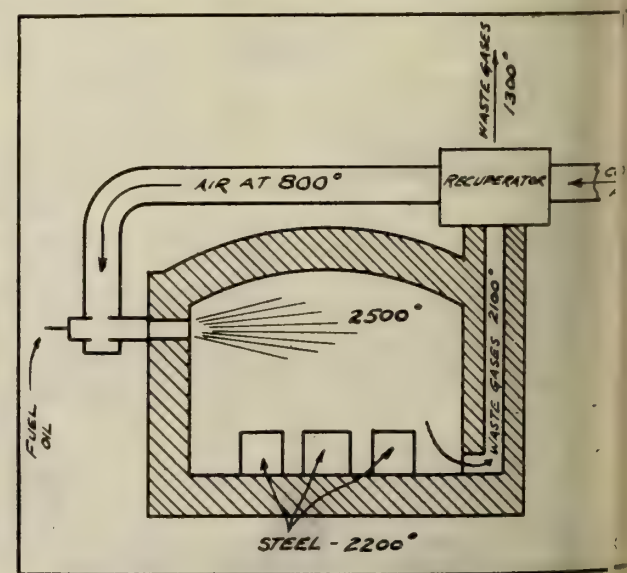

Fig. 3.—Diagram of recuperative type of forging furnace.

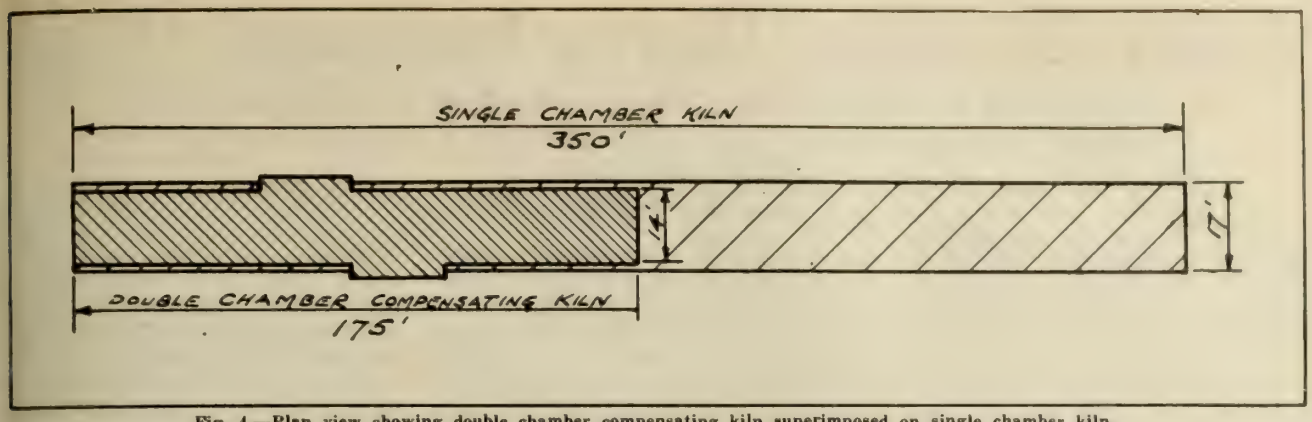

Fig. 4.—Plan view showing double chamber compensating kiln superimposed on single chamber kiln.

at loss per sq. foot of wall per hour

$$= \frac{A \times F (T_1 - T_2)}{B}$$

$$= \frac{1 \times 7 \times (2500 - 100}{9}$$

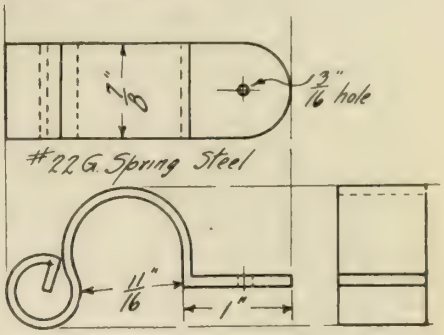
= 1870 B. T. U.

Next consider the heat loss when the vll consists of 9 in. firebrick × 4½ in. o heat insulating material having heat r isting qualities 8 times as great as f brick. This 13½ in. combination wall is equivalent to a firebrick wall 9 in. >4½ × 8 = 45 in. thick.

Heat loss per sq. ft. of wall per hour

$$= \frac{1 \times 7 \times (2500 - 100)}{45}$$

= 374 B. T. U.



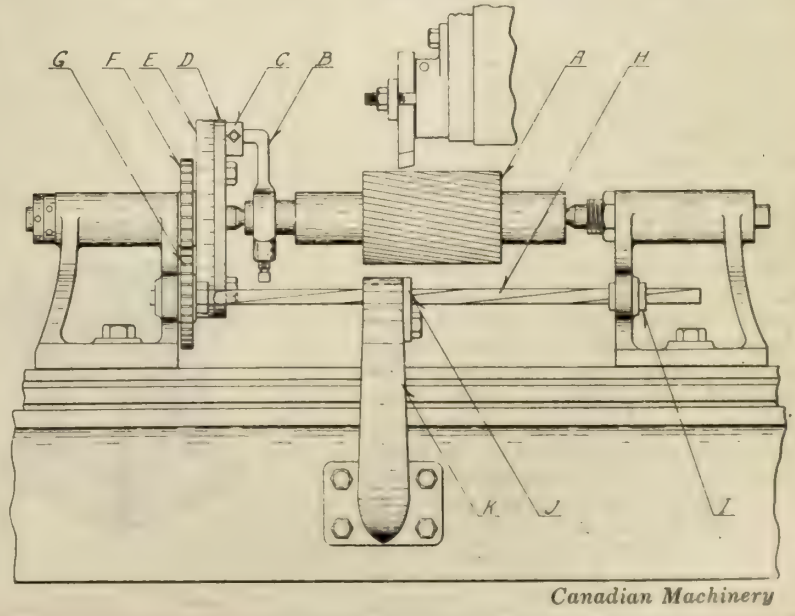
he above comparison shows that by pper design 4/5 of the radiation losses c be eliminated. A forging furnace wn heating chamber 5 ft. long, 3 ft. we and 2 ft. high, built with firebrick wls 9 ins. thick and having an oil con- mption of 20 gallons per ton of steel ted has a radiation loss of 8 per cent. of he total heat supplied. 4/5 of this loss mover 6 per cent. of the fuel can be ved by proper wall design. As radia- tn losses increase in direct proportion wn the total exposed wall surface of a rnace great fuel savings are possible by a design which will give a maximum output of material heated for a given size of furnace.

Figs. 4 and 5 illustrate what has been accomplished in the way of reducing wall surface for a given furnace output. These views show a double chamber compensating annealing kiln, of one design, superimposed on a single chamber continuous annealing kiln. Both kilns shown have a capacity of 50 tons of annealed malleable iron per 24-hour day. It will be noted that the exposed wall surface of the double chamber kiln is less than half of that of the single chamber kiln. The cost of fuel per year for many furnaces in use to-day, is several times the original cost of the furnace itself. This being the case, furnaces of modern design having high thermal efficiency quickly pay for themselves in fuel saved.

INFORMATION WANTED

A manufacturer in the Western part of Canada is anxious to procure a number of No. 22 gauge spring steel clips as shown in the illustration. He states that what he wants is prices on one thousand lots, and we take it from his correspondence, that he expects the cost of dies to be mentioned as a separate item.

Believing that manufacturers in the east might be interested, we show the clip with three of its chief dimensions. Anyone who feels that he is in a position to handle this work can write us stating prices, etc., when we in turn will pass the information to our correspondent.



Showing the part under discussion.

HOW ABOUT THIS?

In the June 30 issue of Canadian Machinery M. C. Allen contributed an article. A check was forwarded to the address given us, but same was returned marked "Not at this address." If Mr. Allen will forward us his new address we will once more send out the check.

Planing Helical Grooves

The sketch illustrates a fixture used on a planer for cutting helical grooves on a crusher roll. The work "A" is supported on centers. On one end is the driving dog "B," the tail of which is located in the slot of the lug "C"—back lash being taken up by the small set screws. Plate "D" is independent from plate "E," and may be revolved by slackening two nuts, the bolt heads moving in T-slots in plate "E." Plate E and gear "F" are keyed to the spindle in the drive head. Gear "G," which meshes with gear "F," is secured to the square twisted (and milled) shaft "H," this shaft being supported in lugs extending out from either head, the bushing "I" in the right hand head providing a cylindrical bearing. "J" is a flanged bush fitted to shaft "H" and secured to bracket "K." This bracket is bolted to the planer bed. Movement of the planer table rotates roll while tool is cutting. Adjustment for different cuts is made by movement of plate "D" to the desired setting, graduations being provided for this purpose.

Canadian Machinery

Making Embossing Dies for Emblematic Work

Work Can Be Divided Into Three Classes from the Die Sinkers Angle — The Hub Method — The Cut in System, Also the Combination Method

By CHAS. E. HALL

THE making and use of embossing dies for emblematic work, and jewelery especially, seems to be confined almost exclusively to the jewelry trade. While several of the sheet metal stamping plants do a little embossed work, such as checks, key tags and work of a similar nature, the dies from which these articles are struck are necessarily in a cheaper class than their more exalted brothers of the jewelry trade.

Perhaps, in a description of some of the latter kind, it will be well to divide it into three classes, viewing the subject from the die-sinker's angle. They are: The "hub method," the "cut in" or engraved method, and lastly, a combination of the two, where the design is "hubbed" in part, and the balance cut by hand.

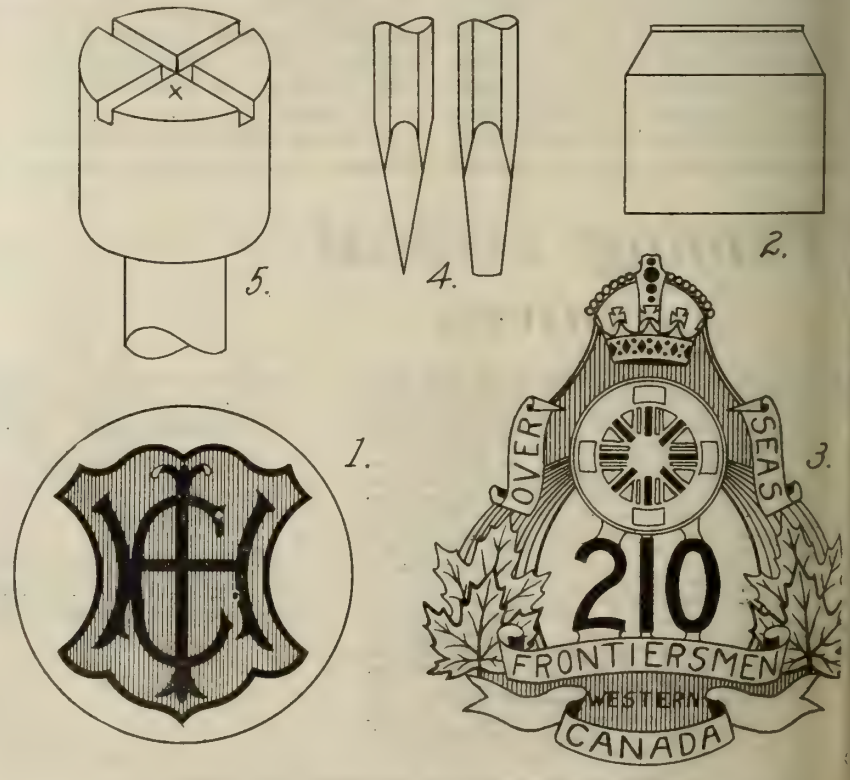
The hub method is used for all enamelled work, such as society buttons, emblematic goods, etc. The chief reason for this is on account of all parts of the die being of a uniform depth; the work struck from it for enamelling being also perfectly level; consequently when it is stoned off on the surface there are no low spots which would otherwise result if the die was cut by hand.

Another point in favor of the "hub" method is the fact that once the hub is made as many dies can be produced from it as may be required, and each will be the exact counterpart of the others.

To make the "hub" various means are adopted, according to the job itself, and also the equipment available. A good rule in the roughing out is to make use of any method, orthodox or otherwise, which makes for the rapid removal of the surplus stock.

Taking Fig. 1 as a simple example, the design being a shield enclosing a monogram, both being in relief, the background being removed by the most convenient method.

By using a die-sinker's hand-piece with a coarse "Revelation" dental burr of the wheel type, the outline can be milled out so that very little hand work with the graver will be necessary. Merely a touch-up here and there, particularly in the corners of the design. The surrounding metal can be turned off in the lathe as near to the outline of the shield as possible, and the small pieces remaining knocked off with a small chisel, the rags being removed by filing. The monogram and the inside outline of the shield (This is not Irish) are then outlined with the graver. The background is drilled away with the hand-piece, the remaining surplus metal being cut away with gravers of suitable shapes, the complete design being next trued up. The design now stands out in relief, and the surface, which was smooth to start with, is now stoned slightly with an Arkansas slip stone to remove any slight burrs which may possibly have been left. The hub should be bevelled back from the edges of the design, as shown at Fig. 2, to eliminate the risk of the thin, raised outline cracking in the hardening process; for if the edges rose abruptly from a flat background they would experience a sudden contraction on quenching, while the body of the "hub" would cool more slowly on account of its relative bulk. It is now ready to harden, after which the temper is drawn somewhat, and it is ready for use.



Die Block

A suitable die block of annealed steel is selected; faced up parallel with the back; and the front smoothed up on a fine emery paper lap. The hub is placed face downwards on the die block in a central position, and a light blow with the drop-hammer gives the impression. If the hub has any comparatively large flat areas in relation to the other parts of the design it is struck just hard enough to mark the impression and the lines on the die are cut away roughly by hand. The hub is replaced an struck again to the required depth. Th is to overcome the tendency of the large surfaces of the hub to carry down th surrounding background of the die ar also to prevent any undue strains bein established by the displacement of th steel.

When the desired impression has be obtained the die-block is placed in th lathe chuck and faced off to leave th required depth of impression. It is th polished on the face and is ready harden. Powdered boric acid is dust on the face of the die and the block heated in a semi-muffle gas furnac When at a low red heat it is remov and the boric acid is smoothed over t surface with a strip of brass to elim nate any air bubbles. It is then placed in the furnace and brought to t required temperature, varying in degr with different grades of steel, a quenched, face upwards, under runni water. It is then re-heated to abo 350 degrees F., slightly quenched, a allowed to cool off to relieve any strai It is next scratch-brushed. The bor acid leaves the surface perfectly cle which is most important in this cl of work, and the die is now ready use.

"Cut In" Method.

In regard to the "cut in" method, lit

Figs. 1 to 5, showing the dies made and the tools used.

ed be said here, as it is more or less die-engraver's job, and is one of artis- taste, skill of hand and the result of ng practice. If the die is of consider- le depth or area, the outline is traced the coppered surface of the block, d the surplus metal removed with all chisels of various shapes, also by all grinding wheels held in the hand- ce, while the balance is cut in with avers.

Impressions in plasticine, which has d some suitable dry color added to event it from sticking to the die, are ken from time to time as the work ogresses, to enable the die-sinker to l just where the metal needs to be moved. The plasticine is stuck on a all piece of steel, placed on the die, d struck a sharp, light blow with a mmer to embed it into all parts of e die. By breathing on the die sur- e, just enough moisture results to event sticking. When finished, the me procedure as in the foregoing case employed.

The Third Method

n the third method, where both "hub- " and "hand work" are resorted to, very wide field opens up, so that it will ot be possible to just "scratch the face" as it were and give one example atypical of the lot. Of course work nthis field is so varied in size and sign that no hard and fast rule can elaid down. Again, one die-sinker ay follow the "hub method," while an- ther would adopt the "cut in" way of ing the same job, and each get equally od results in about the same time ex- eeled. Numerous hand punches and ler stamps also enter into this class f work; and sometimes it is advisable o make a punch or hub for some par- icular part of a die which could be cut n y hand in less time. But if other ol are on hand or in prospect, where th particular detail is to be used, the in saved on the second die more than offsets the extra time taken in making a ub or punch. This applies to mili- tar cap badge dies, taking the crown as n example. In submitting a new desn, it is always advisable to use suc details as may be on hand in the wa of punches, hubs, etc. This also ena es one to make a much closer esti- ma of the cost of the dies than would oth wise be possible if every detail had to be made before starting the wo .

I Fig. 3, which was the cap badge for he 210th, Frontiersmen Battalion, we have an example embodying all three methods. This was made in two pieces on account of the way in which the badge was to be finished. The body of e badge was oxidized and brush- finished to a dark olive green tone, while the centre, enamelled in three colors, red, white and blue, was finished in gilt, afterwards being soft soldered on the badge. The die for the enamelled centre was made from a hub and the work trimmed after being struck in a round punching die of suitable size. The let- tering in the centre of this piece, which was "God Guard Thee," was punched in the hub with very small letter stamps. The wording had to go inside of a 5-32-inch circle, and as the letters were to be enamelled in blue, they had to be very distinct, and the small space they were to go in left no room for error.

Die For Badge

The die for the badge proper was made as follows. A hub was made for the circle which encloses the enamelled centre, and the figures "210" were sunk in the die block. The outline was then marked on, and the crown, which was a stock punch, sunk in its proper position. The maple leaves, also stock punches, were then sunk with a light drop-hammer by marking and relieving to prevent pulling down the background as before stated. The ribbons were then outlined and cut in, using small chisels for roughing out and shaping them up with the graver. The raised edges of the ribbons were punched in with a punch known as a tracer by tapping lightly with a hammer and moving it along at the same time. Tracers are made of various widths and curves and are left straight on one side, as shown at Fig. 4. The straight side enables the punch to follow curves of different radii and leaves a very smooth polished surface when carefully done. The background of the ribbons was next tapped all over with a matting tool, very small on the end, and having about seven small raised dots on it.

The lettering was then put in with die letter stamps which are the other way round to the ordinary variety, as they give a reversed impression.

Here it may be well to mention that hubs and detail punches are made the same as the finished work; while all work done on the die proper is reversed. The remaining background of the die was cut by hand and rounded out where needed, smoothed up, and the die hardened.

The background of this particular badge was cut away between the figures "210" and the maple leaf border with piercing dies and made a rather attractive-looking badge when completed.

This badge was struck from bronze plate .035 inch in thickness, and cut in squares with a shearing die. As the die was comparatively deep in the crown and ribbons, it is obvious that a full impression could not be brought up in one blow of the drop-hammer, if a flat face were used in the head, so that in work of this kind a male die is employed. When the female or die proper is completed, it is securely fastened in the bolster of th drop-hammer, and a "jack" die as shown at Fig. 5 inserted in the hammer head to carry the male die.

The jack die is about 3 inches in diameter with two slots planed across it at right angles to each other, both being about 1-4 inches wide and 3-16 inches deep. A small index mark is made in one corner near the centre, to insure re placing the male die the same way after each blow after starting to strike it up. The jack die is left dead hard.

Making the Male Die.

We are now ready to proceed with the male die. A round annealed block of tool steel about 2 inches in diameter and 2¼ inches long (in this case) and slightly domed on the face is now taken and the back end roughed out on the shaper to approximately fit the slots in the jack. It is then heated to a bright red and placed face downwards on the die with the roughed-out ridges so placed that they will enter the slots when the hammer descends. A top blow, in this case about 4 feet 6 inches with a 150 lb. hammer head is given. It is replaced—having regard to the index mark—as quickly as possible, and the blows repeated as long as the block remains red. Usually after a couple of blows at the most, the slots of the jack engage it, so that repeated blows can be rapidly given. It is then allowed to cool off and the background relieved by chiselling or etching. It is re-heated, and the same procedure continued until a full reversed impression of the die is obtained. The background surrounding the design, also the parts to be removed afterwards in the piercing operation, are etched away slightly to within about 1-32 inches of the outline of the design. This is to allow the whole of the blow to be struck directly over the impression in the die, part of the force of which would otherwise be expended in pounding out the surplus metal of the square blank used. The male die is now a perfect fit in the die proper, and it is obvious that a knife-edged impression would result after the trimming operation. To obviate this defect, the male die is trimmed with the graver, removing about 1-6 inch all around the outline, making it just that much smaller than the die itself.

When the articles are struck, the metal flows into the intervening space between the two dies, and gives a substantial edge when trimmed out. On account of the male die being hot when struck, a certain amount of shrinkage takes place on cooling, which causes a loose fit in the slots of the jack. This is overcome by peening out the raised ridges on the male die with a ball peen hammer. It is now hardened; the temper drawn to a dark purple color, when it is ready for use. By placing it on the die and giving it a slight tap with the drop hammer, it again fits snugly in its place in the jack, where it is securely held till the job is finished.

In regard to donning the face of the male die on starting, this particular shape will vary according to the shape and depth of the die itself, and often a sharp cone shape will be preferable. A little forethought and judgment as to the proper shape to start with, will greatly facilitate the striking up of a good impression.

Sometimes when hand cutting has been employed, the general effect is

often enhanced by lightly sand-blasting the die before hardening; but this depends largely on the finish the struck articles are to receive. Again, some dies, depending on the design, give very artistic results by sandblasting part and polishing the flat surfaces of the background to a mirrow finish.

When a sandblasting outfit is not available, a somewhat similar result is obtained by warming the die and pouring a little hydrochloric acid, for a few seconds only, over the surface, immediately washing it off. This has to be done very carefully, otherwise any fine lines may be destroyed. The sandblasting is preferable as the die can be examined at any time as to the result; and again, parts can be blocked off with plasticene if it is desirable to leave them smooth.

In regard to the spacing of letters, this is a matter of skill and practice. A good way is to take a plasticene impression of die to be lettered and select a stamp of suitable height for the space, and if say, 60 letters had to go in a given length, just tick off the impression with the stamps, allowing for space between words, and see if the stamp you are using will go 60 times into the space. If it will, you start and very lightly stamp them in the die, using the impression as an approximate guide, moving any letters a little where the spacing is faulty,. When properly spaced, sink them a little deeper, going over the lot gradually, taking impressions at frequent intervals to avoid stamping some deeper than others.

Impressions from an accurately lettered die look well when finished; while one letter out of alignment sticks out like a sore finger.

When the letters are all stamped in, the background will be found to have risen slightly. This is filed down level if the lettering is on a flat surface and stoned smooth or removed with the graver or riffle files; or sometimes with a small carborundum wheel held in the die-sinker's handpiece, according to the accessibility of the work. It is next stoned smooth or matter according to the requirements of the case. This also removes any doubled impressions which may have resulted in the first marking of the letters; hence the necessity of very light stamping until perfectly sure of the spacing.

It is hoped that this will give a general idea of the ordinary run of this class of work, and while volumes would be required to completely cover the field, enough has been given to show the nature of the problems on hand.

The Alfred Herbert Ltd., have sent to those whom they believe will be interested, a very attractive invitation to visit their machinery stands at the Toronto Exhibition. Canadian Machinery has received one of these invitations and cannot help but comment on the neatness and taste displayed in its preparation.

Reduce Accidents By Instruction In Efficient Safety Method

*By C. A. KUECHENMEISTER

I BELIEVE the one black mark against industry during the past few years is the fact that we all thought we could not enforce safety rules and safeguard our shops because we couldn't get men. Factory inspectors would console us with the information that of course we couldn't be expected to do much safety work, guard building, rule enforcing, etc., because labor was so scarce, and we used every excuse we could lay our hands on, with the result that it cost the industries of Ontario over $7,000,000, and we injured a man every three minutes of every working day of last year.

Scarcity of labor the cause of it? Lack of interest in safety was the cause of it all! Don't blame the workman for a lack of interest in guards, safety appliances and safety rules when we all sit back and admit—tacitly at least—that while we know how to prevent machine smashing that we are helpless in preventing the recking of human beings. And this year the excuse is that our shops are practically shut down and we are not busy enough to warrant doing safety work.

I do not believe that we can divide the word safety into classes and say that we are going to do industrial safety, public safety or school safety. Neither do I believe that any group of men can organize into an association and say they will do one class of work to the exclusion of any of the other, and succeed. And I will go a little farther and say that I do not believe you can organize your plant for safety and not do safety work outside of the plant if you hope to interest men in safety.

To the man who has kept up-to-date and has tried out all the safety suggestions; who has interested the manager, superintendent and foreman; who has organized committees and guarded machinery, and who feels that the desired results are still in the distant future I want to give a significant and far reaching statement recently made by the National Safety Council. A statement that I believe is the answer to our problem of interesting everybody in safety; the statement that over 75 per cent. of all accidents can be prevented, and that only by community effort can that be accomplished.

When you give serious thought to the last part of that statement a new vision comes to you and you wonder why on earth it wasn't thought of long ago. If you go at the problem of interesting everybody in safety as a community effort you immediately have access to every educational and civic agency in the community. While the word safety cannot be divided into definite class and be treated as such, you can, however, teach safety through the schoo in the home, by use of law making a law enforcing agencies and in the indu tries, and by doing so you get results.

Through the Schools

It seems to be generally agreed th teaching safety to the children in t schools is the logical and proper pla to begin. Many a workman who thoug he knew how to take care of himself the shop and refused to believe that could be taught how to be more care has been won to the cause by his ch coming home from school and talki safety to him.

Certain conclusions may be dra from the study I have made. They a

Accidents are not a necessary e They can be reduced. This reduct takes place as a result of continu educational campaign. This cannot obtained by spasmodic and unrela campaigns. The tendency for auto bile accidents to increase is proporti ate with the increase in automo registration. The departure from in 1920 was due to the safety campa Increase in population does not app to bear a very close relationship to number of accidents. The schools the logical places to begin this educa programme.

Teaching safety in the schools an the court room will not only stop m of our street tragedies but they will the safety man in the shop reduce a dents. If his work is nicely co-ordin with the work being carried on out he will quickly see results.

Another conclusion I have come t that safety is not, primarily, a pro for individual industrial plants to s When a man comes to us and asks f job and says he is a machinist, we k and he knows, what qualifications claims to possess. We know he im that he can start and stop machines up jobs, use calipers and read m meters. When he gets into the and is given a job he has never before he asks the foreman a few tions, the high points are explained he turns out the work.

This is true because years ago organized guilds and developed th prentice system. They set up stan and before a man was a journeym had to qualify. The guilds and ap tice system have almost disappeare the standards set up by them are in use. If working safely was pa the old standards, unfortunately i been lost and so we must find a w put the fundamentals of safe livin working into the training of the man.

*From an address delivered before Safety Convention at Toronto.

Machining Adjusting Nut in Eleven Minutes

By H. A. LOUDON

THE piece being machined is made from tool steel blanks cut from the bar. Two finished pieces are ade from one blank at one setting. he cutting off tool does not divide the ro pieces until they are both complete- finished. The advantages gained by achining the piece in this manner are, 1st, it is quicker, the boring and turn- g cuts are both taken at the same time. the pieces were machined one at a ne they would have to be gripped on e outside and bored and threaded in e first operation, and held on a thread- fixture while the outside was being ned on the second operation. Not only would the machining time longer if the piece were done in this nner, but more time would also have t be spent by the operator due to the f t that he would have to make two t l set-ups on the piece instead of one. nd, it is more accurate. The sur- f es all being machined at one setting. rd, and most important of all, i that the tendency to distort under t pressure of the jaws is greatly re- d ed due to the resistance of two pieces i ead of one, and to the fact that it is gripped on the other end from that w ked on.

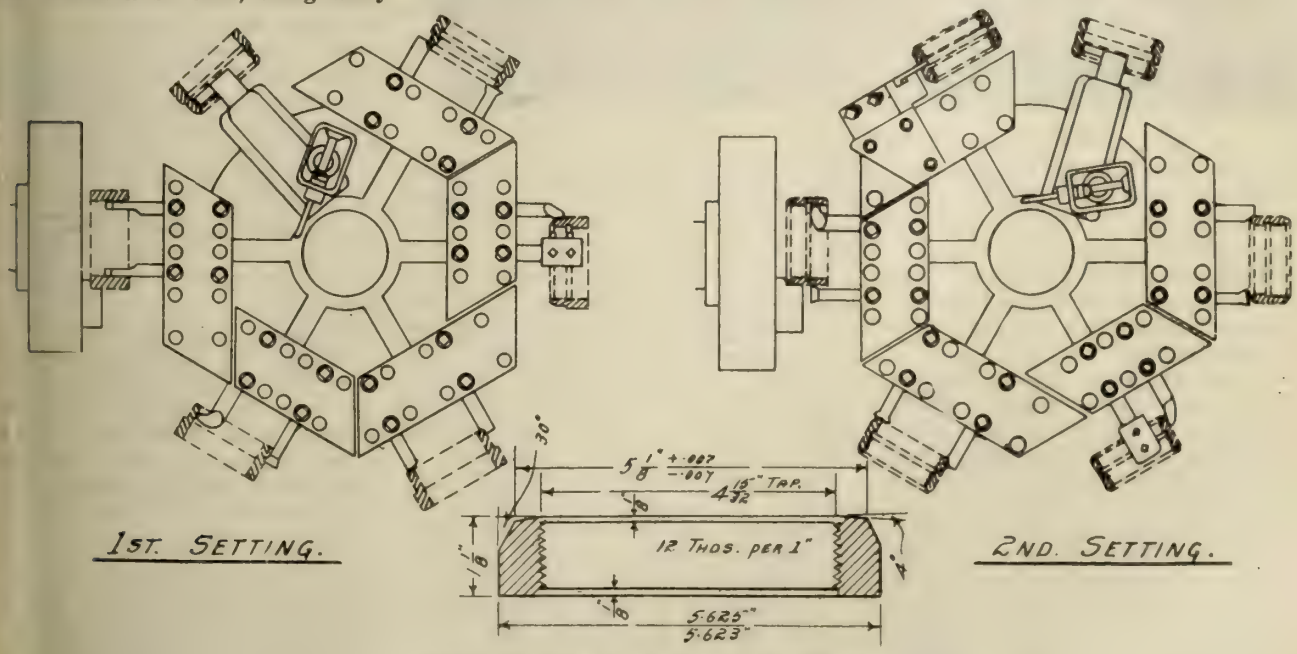
The work to be done, showing stages of completion.

First Operation

he work is gripped in a three-jaw ck, and in the first position of the ret the blank is cored half way ough. It is then taken out, re- ed in the chuck, and the other half od. Coring in this manner has two antages over coring the piece ight through in one position, viz.: ter tools can be used, doing away with overhang, and narrower tools can be used which means a saving in stock. It is good practice to save the cores and use them for small gears.

In the second position of the turret, two tools of the inserted cutter type, simultaneously rough turn and rough bore.

In the third position the bevel is roughed and the 4 degree angle is butt-faced.



In the fourth position the outside diameter is finish turned. The cross feed is then thrown in, and the cross sliding head moves across on its broad-spread bearings, and the grooves are cut.

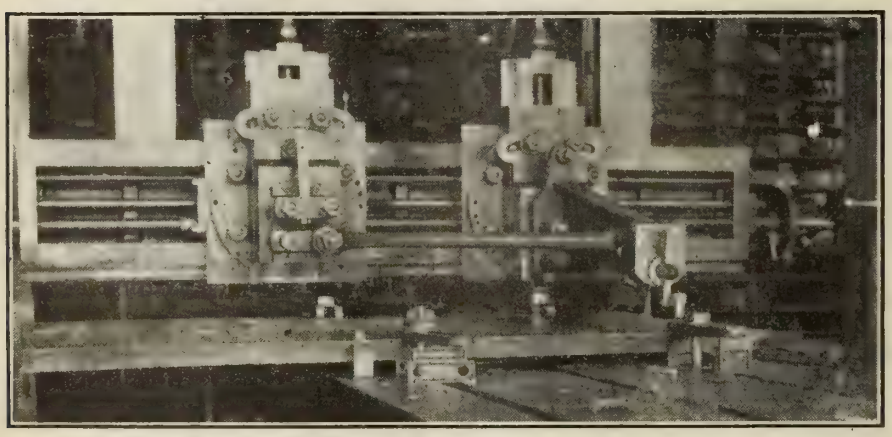
In the fifth position the bevel and 4 degree angle roughed in the third position are finished.

In the sixth and final position the piece is threaded by the Hartness screw thread chasing attachment. This attachment is automatic. The carriage is locked to the bed, and the attachment gets its positive drive from the work spindle. The threading tools feeds forward at cutting depth under lead screw control until the tool bar strikes the stop. The tool then automatically withdraws to clear the work and returns at high speed to the starting point, where it again feeds into cutting depth and engages the lead screw. The work spindle revolves continuously. The only motion required of the operator is that of adjusting the cross sliding head forward a slight amount during the return of the cutter to feed the tool in for the new cut.

Second Operation

In the second operation the piece is reversed and gripped on the finished outside diameter. The second operation is exactly the same as the first except that a cutting off tool is inserted in place of the coring tools in the first operation, to part the finished pieces. Production time, for the two finished pieces, is 23 minutes. This gives an average daily production time of one finished piece every 11½ minutes.

Showing the layout of the tools for both settings.



Efficient Planer Practice—Points to Watch

Setting of Work is Just Important—Flat Shims are Better Than Tapered Shims—The Cost of Belts—The Importance of Neatness —Painting Castings to Help The Planer Hand.

By DONALD A. HAMPSON

MOST planers have the rack screwed or bolted to the table. Smaller machines have filister head screws with the heads set in flush with the middle slot. We had some of the latter type, rather old, in our planer department but all running every day on work within their capacity. It was a daily task to get a big screw driver and tighten up these rack screws: the boys did that as religiously as they oiled up; no one seemed to think of the time so lost and none seemed to mind the "chug, chug" of the rack at reversals.

A new foreman came along. One of the first things he did was to take the planers out of service, one by one, and put a key in each piece of rack. These keys were of one-half inch square C. D. S. and were set half in the rack and half in the under side of the table. A piece of steel of this size, crosswise of the rack presented double the shearing area of the screws and it stopped for all time the noise and delay.

Showing how to make the extension head rigid.

Setting up work is the most important part of "running a planer." If a piece is improperly held, it may be sprung out of shape so much that no amount of careful machining can ever make it true, or it may come loose under pressure of the cut and have to be set all over again.

The angle of rake on planer tools is so slight that we may almost consider the effects as if the tool stood at right angles to the table. This latter would make all the stresses from cutting in the direction of the table's length. There is, however, a slight angle in two directions which divides the thrust of the cut into three components, the greatest of which is by far the longitudinal. Hence the cardinal rule for setting up is, first, place enough posts to resist all thrusts. Clamps are all right and very necessary, but two posts in front of a job are better than a dozen clamps; if the job is narrow, only one post is necessary. If it is wide, two are set in place and as far apart as the width of the job and the table spacing will permit.

After the posts are set, two clamps (or fingers) are added to keep the work in place. The fewer clamps used, the fewer bolts there will be in the way of the tool. One of the fundamentals taught in machine design is to make all parts subject to stress positively held, not depending on friction. This applies with equal force to planer setups. An incidental advantage of posts is that they do not distort the work.

Castings require more care in setting up than do steel parts like bars and forgings. Often the time required to properly pack up the work runs into hours. A good assortment of shim material is most essential. This should run in thickness from thin tin to nearly one-half inch; and it should be flat, and free from burrs or bends, and there should be a sufficient variety of sizes so that two or three pieces are the most that will be required to build up to any space.

Flat shims are better than taper ones. Even though clamps are securely tightened over taper pieces, the combination of reversal shocks and the angle of inclination frequently loosen up the shims. This will not occur with flat pieces. Except on the roughest work, taper shims should not be tolerated.

There should always be packing under clamps. If there is not, the work will be sprung when clamped and many guesses made afterwards as to why it is out. The writer has known cases where the accuracy of the cross rail was questioned; all the fits in the head joints came in for "knocking," and considerable time was spent in re-aligning when the sole trouble was that the packi was springy. No job will come out tr when it is held distorted for cutti There is an impression that looseni up for the finishing cut will insure accurate job—why loosen up? It simply an acknowledgment of impro clamping. Castings spring when outer skin is taken off. It is necess to re-pack to finish after that, but lo ening the clamps will not help out.

Leather belting reached its high price a couple of years ago. cause of their weave, the ma factured belts were not used much for mechanically shifted dri as for constant speed work, though r er forks eliminated fraying quite s cessfully. Our shop substituted wo belts wherever they could and, tho skeptical as to their standing up, tried them on planer shifting dri Several years of service have pro them satisfactory, if a belt with the per kind of edge binding is selected

We opened up all the shifting fo or loops, giving them a generous mouth top and bottom so there w be no sharp corners to catch. After belt had been cut to length, the were stuck in the glue pot and this allowed to dry before putting the bel service; by this means, a binder formed for the cut ends of the fibre

In the field of general work, it is dom possible to make full use of all "features" of a machine tool—mul heads and spindles, all gear feeds, q changes, flow of coolant, speeded movements. Generally you can re on about one of these per job. two or four heads on a planer, fo stance. Often it takes more time t the extra tools than is saved by use, while again, the work seem "run in bunches" of a class where can use but one head at a time. rare occasions, it is possible to re on the extra head, this holding esp ly true when two separate jobs ar up on one machine and running a same time.

On one occasion there happened a number of cross bars of the length for a series of special mac and only one machine available planing them. The planer hand a helper set up the two in the ord time of one, and from then on the ing time was cut in two.

Costs of Belts

The cost of maintenance of the shifting belts may be lessened little attention to the pulleys. countershaft should be parallel wit planer first shaft. in both direc

Make sure that the pulleys overhead line with those below, for if they do not, the forward belt will rub on the large countershaft pulley, resulting in torn edges and broken fastenings. On planers that have run a long time and without proper attention being paid to shifting, the pulleys actually get worn in size and shape. With a single driving pulley between the loose pulleys, the driving pulley gets worn down so much that the belt is loose when shifted on it. This affects the power, and the remedy is either to build up the center one, or turn down the outside ones; always preferably making the center pulley slightly larger than the others.

On the countershaft, the driving pulleys often have a flat face. This makes it possible for the belts to creep at will (within certain limits) with the result that the one on the smaller pulley rubs against the larger pulley. The remedy is to crown these pulleys. The writer received a motor-driven switch and frog planer from the makers with the two overhead pulleys flat face, with the result we were immediately troubled with frayed edges and stretched sides on the belts, and not until the pulleys had been crowned more than an eighth of an inch did we overcome the trouble.

Be Orderly

Neatness and orderliness are homely virtues but nowhere are they more acceptable than around a planer. Some men always have a mess about their machine; floor thick with chips, boxes and angle plates blocking the way, and the table piled high with bolts, dirt, and junk. They have to clear a spot before they can put on another job, and before they can do that, the whole collection has to be scraped off on the floor to allow bolts to be run in the proper slots.

The orderly man never has a littered table and his floor is always navigable. As soon as his cut is going, he puts away bolts and packing, takes a broom or brush and sweeps the chips into a neat pile under the machine, and arranges his accessories generally. Usually that man is keeping another machine going too. He always seems to do his work with little effort, even to the point of appearing lazy in his movements. One such man adopted the kink of catching the chips from side cuts in a keg placed under the tool; his work involved making a side cut on each side of an overhanging casting but, instead of the usual heap of chips, he caught them in the keg which was easily emptied.

Moving a Planer

A planer seems like an awkward machine to move but it is not difficult to do so if the matter is given a little forethought. It may be that the machine is a new one and has been delivered outside the door by truckmen, or there may be a rearranging of shop tools that necessitates removal to a new location. The first thing is to lay out the position full size of the floor. If the floor is concrete and the bull gear extends below the floor level, a pit must be dug. This pit ought to be several inches larger than the gear all around to allow clearance for dirt and chips that may get in the pit, as well as to compensate for any error in measurement. With some machines, it is absolutely necessary to bolt them down because of the shock of reversal or their lightness. With others there is ample weight to keep them in place. The best plan in any case is to include bolts or positive stops, though past experiences with the same tool will serve as a guide in this respect.

A foundation that is premanent must always be provided, whether the machine is light or heavy, especially if accurate work is to be done. To one who has never had experience with planers, the ease with which a heavy bed of deep girder type will spring or sag will come as a shock. Planer manufacturers supply a shoe with an inclined upper face upon which a wedge is moved, backed up by an adjusting screw; the shoe is set firmly in the concrete foundation or bolted to the floor. If the former, the machine is leveled up once and for all; if the latter, the accuracy of the ways should be tested at regular intervals to guard against floor changes. These wedge adjusters may be shop-made if desired, and one should go under each point of support.

A good spirit level is all that is needed to level up, or align, a planer. Tests should be made of the ways longitudinally and crosswise, making these tests every two feet throughout the length. The degree of accuracy attainable with a good level is probably not appreciated by mechanics generally, for a movement of one-sixteenth of the bubble, reflects an error of .009 in. at the end of an 18-inch level.

Returning to the subject of moving the machine. If the tool is a new one it arrives on skids and these ought to be left under until the planer is placed directly over its final location. It must then be blocked up while the skids are removed and following this it is carefully lowered by means of jacks, lowering but a little at a time so as to keep an approximate level during the process. To get the machine to the location from the shipping door, rollers must be kept under the skids, and the assembly moved either by blocks or crow bars. If bars are used, six men can move a 14-ton machine along a hard concrete floor.

An ordinary chain block such as found in all shops, or a rope tackle may be used to advantage. The fixed end is attached to a post or a heavier machine, or it may be necessary to run a rope to a distant doorway, placing a beam across this for a tie. In all cases, the effect upon the fixed member in the shop must be considered and its strength to bear the load. A portable shop crane or hoist may frequently be used to advantage for pulling, by blocking it between posts or at a doorway, detaching the chain overhead, and running this out horizontally; then the winch is used to do the hauling.

Where the distance to be moved is only a few feet, and it is undesirable to string tackle about, one man can move the average planer up to 24-in. size. It is neither desirable nor advantageous to re-skid a machine for a shift even for as long a distance as a hundred feet unless the floor is in very bad shape. In one instance the writer saw a 24-in. and an 18-in. machine moved six feet to the right of their old location. The man doing the work shifted them both, had them lined, (but not leveled) all in an hour, and his only tool was a six-foot bar—with a fulcrum set under the bar, and set within two inches of the machine. He worked one end, and then the other at a rapid rate, without undue exertion. Sometimes the location is so cramped that the bar is the only method that can be employed and the machine has to be worked along by a movement that resembles "tacking" in sail boat handling.

Painting Castings

Where iron castings are not tumbled or sand blasted all over, the jarring loose of particles of moulding sand is very annoying to men on the planer. The writer adopted a method of painting such castings with gratifying results. Exterior parts were of course cleaned before putting on the machine, but the under sides of beds and frames were not. It was for such places that the painting was helpful and the time saved the planer men more than paid the cost of a coat of cheap paint, the purpose of which was to hold any particles that would jar loose.

Chips from the planer are usually a dead loss; junk men will not take them, larger dealers in old metal will not bother with less than a carload lot, and local foundries do not have facilities for remelting. Where one or more machines run on cast iron exclusively, the chips may be collected and used about the yard. Mixed with ashes, they make a fine hard roadway, or drive, and the same is true of walks about the yard. The weight of the cast iron practically guarantees its "staying put" no matter how hard the rain may be and it soon rusts enough to become a binder with any material. The coarsest roughing chips will not injure rubber tires but this is not true of mixed cuttings with steel shavings mixed in them.

An open side planer is a most convenient tool in any shop, but when you do not have such a machine you have to get along with an extension head. The photo, Fig. 1, shows a method of making the extension more efficient because it is made stiffer. One head only is used on such a job, and if there is a second head on the machine its vertical feed can be engaged to travel in unison with the first head. The triangular brace, which is made of a piece of pipe flattened on the ends, is connected between the end of the extension and the second head. With such an arrange-

ment, it is possible to take good big cuts, and the extension becomes a production tool, not a nibbler to be avoided as long as possible.

Every planer slide should be provided with a lock. Of course, the heads and vertical slides have their gibs and gib screws and these screws ought to be set very carefully, so that the slide moves a little tight rather than loose. The screws should be sealed and any change in their setting absolutely forbidden. The fit thus created is free enough to permit hand and power feeds without undue strain, yet it is snug enough to maintain a setting throughout any ordinary period of cutting. One of the screws on the vertical (tool) slide, and one on the head (at the top of the rail) should be replaced with a binder, or locking screw, to lock the slide while the other slide is feeding. Thus, the lock on the head is tightened, while a side or facing cut is taken. It is sometimes argued that a properly fitted slide will keep itself in place,—and there is some truth in the remark— but locks all around will pay for themselves on any planer.

Watch Your Methods

An investigation made to determine why one man had no trouble with his tool holders while all the others asked for replacements at intervals led to an adoption of this man's method throughout the shop. The other planer hands broke set screws and chewed out the threads and ground away the ends of the holders. Armstrong holders for one-half inch and five-eighths in. bits were used. Without advertising it all, Steve always removed his bits for sharpening. He said when he ground them in place his set screws got rusty, the rust worked down inside, and the screws stuck, and then they had to use a big wrench to get them loose. Getting them loose, together with the big-wrench habit acquired, broke screws and stripped out threads. But though he did not get them rusty, Steve took his screws out occasionally and oiled them; and for grinding bits that were too short to hold in the hand, he used a cracked holder that one of the other boys had thrown away, this saving his good one.

Cast iron takes a beautiful finish when a broad tool is used. This may be either a "scoop" tool, or a spring tool. Feeds as high as ½in are possible when the flat face of the tool is machine ground & the tool is correctly set. The end of any such finishing tool should be .001 in. or .002 in. convex & the corners rounded. Such a shape will not scratch, and if set so that the leading side is the higher while the other side removes the merest powder, then the finish will be first class and the accuracy in line with the best work.

The finishing tool should not remove too much metal at a cut. Different grades of work call for different standards; rough work would be finished with a flat scoop tool that removed perhaps 1-32 in., while the final cut on an accurate piece of relatively light section would be made with a goose-neck tool that was removing not over .005 in. and had been preceded by a semi-finishing cut. Before the finishing cuts are made on a casting, the cross rail should be wiped off underneath to remove drops of oil which might fall on the work and form a glazed spot over which the tool would jump, or "skate." Greasy fingers will form the same kind of a spot. Sometimes a casting that has been oiled once has to be planed again to a nice finish; in such a case, a round nose tool is better than a flat one for the latter will not take a light cut over a glassy surface.

REDUCE ACCIDENTS

(Continued from page 38)

We must find a way to so thoroughly impress safety upon future workmen that when they come to the plant they will exercise care in all things.

Guarding Machines

Then there is the matter of guarding dangerous machines. The first thing everybody thinks of when you talk about safety in a shop is guarding machinery. The pioneers in the work began with guard building and we must do the same thing. Not only will guards prevent the serious accidents in a plant but they are the only visible part of the safety work. Guards on all machines in a plant will convince workmen that the owners are serious in their efforts to make the shop safe. Guards on only a few machines—the guards that the Government inspector has ordered or forced on to machines —are only glaring, hideous, telltales of the insincerity of the management. If workmen are citizens, haven't they the right to demand safe working conditions? They have, and the sooner it is recognized the better it will be for all of us.

We are assessed "collectively" for the cost of accidents. Why should we not do "collective" accident prevention? Plant managers must submit, without notice, a statement of the annual payroll. Why not have these same managers submit, with due notice, a statement showing what guarded and unguarded machinery they are operating. The result would surprise us and would certainly tend to create interest in safety in the employee who is paid to manage the plant.

TELEPHONIC INSTRUMENTS

Some interesting points on telephone measurements were brought out in a recent paper presented before the Institution of Electrical Engineers in England. Sir William Noble, who was the author, named his paper "The Long-Distance Telephone System of the United Kingdom." Among other things he pointed out that the developments of recent years have extended the practical limits of telephonic science. Thus measurements and adjustments of the capacity and resistance of cable conductors are now made to an extreme degree of accuracy at frequencies of 800 cycles per second and higher. The amplifiers used are exhausted to a pressure of 0.00001 mm. of mercury, probably the highest vacuum employed in commercial apparatus. These methods and devices, the employment of which a few years ago was possible only in the best-equipped laboratories, now form part of the standard construction and operation of a long-distance telephone plant, and are the every-day concern of the telephone engineer.

NON-GLARE LAMPS

A new apparatus has been invented in England which is said to abolish the usual diffused glare from motor car lamps, and enables drivers in the opposite direction to see whether the road is clear. It consists of a grid composed of thin aluminum plates crossing at right angles and forming a network of square tunnels about ⅜-inch wide and 2 inches long. These are held in a frame which fits on to the lamp. The result is that the beam is concentrated about four feet or five feet in front of the lamp, whence it widens out to give sufficient light laterally, while at the same time an increased range directly ahead of some 20 yards compared with bare lamps is obtained.

INTERNAL THREAD GAUGE

John Bath & Co., Worcester, Mass. have developed a micrometer internal thread gauge which enables the measurement of internally threaded parts to be easily accomplished in increments of .0001 in. The gauge enables the determination of the exact amount that a tap cuts over size. Four measuring jaws are held in alignment by closely fitting dovetailed slots in a slide which is operated by a micrometer screw. The moving parts are lapped and fitted so carefully according to the makers, that the gauge is as rigid as a solid plug, and this rigidity causes different persons to obtain the same reading on a given piece.

Three distinct steps are taken in the manufacture to secure a measuring contact that will be as nearly perfect as possible. The jaws are first ground and lapped when set to the nominal size. They are again ground when set to the smallest size, and, finally, when set to the largest dimension. The subsequent grinding relieves the threads on each side of the centre of the measuring jaws. In this way, the threads on the jaws are freed from interference due to the difference between the helix angles obtained at the largest and smallest settings of the gage.

When wear occurs on the measuring jaws, the gage may be referred to a master ring gage and the wear taken up by means of the graduated collar which is provided with serrations that enable adjustments of 0.0001 inch to be made. The gage can be furnished with any number of threads per inch and in nominal sizes of from 1 to 5 inches in diameter.

Electric Furnaces—Points in Operating

Various Reasons Advanced Regarding Type of Furnaces That Should be Used—In Making Small Steel Castings Three Important Points Must be Kept in View

"SHOULD we install acid or basic lined furnaces?" According to F. W. Brooke, vice-president of he Electric Furnace Construction Co., Philadelphia, this query has been asked is company on numerous occasions dur- ng the past six months, and he believes hat the matter to follow will be of in- erest to electric furnace users generally.

"To my mind," comments Mr. Brooke, acid operation should be adopted when:

1. The sulphur in the scrap is and al- ways will be less than the sulphur re- uired in any castings you will be re- uired to make.

2. The phosphorus in the scrap is and lways will be less than the phosphorus equired in any castings you will be re- uired to make.

3. When the range of carbon and sili- on contents will always be wide.

4. When close physical tests have not be met.

5. When power consumption and rate operation are of prime importance.

6. When very small castings are the le output..

Basic operation on the other hand ould be adopted when:—

1. The sulphur in the scrap now, or in ture may go above the limits required chemical or physical tests or re- irements.

3. When the steel has to be made (for emical or physical reasons) to a close rbon, silicon or manganese analysis.

4. When close or good physical tests ve to be met.

5. When alloy steels are ever to be de in the furnace.

6. When steady load is essential.

7. When refining of cast iron is being c sidered.

Reasons 1 and 2 Acid and Basic

A prospective purchaser of an electric f nace, in looking over his available s ap supply, often feels he can obtain a the scrap he requires of a sulphur a phosphorus content low enough (say b w .04 per cent. sulphur and phos- p rus) to meet his requirements. The s ap market and the freight situation, it as been our experience, only too o n upset his calculations, and he is confronted with the problem of having a igh sulphur and phosphorus scrap a a furnace which cannot eliminate h e all important injurious elements. It as often meant one of three things: a paying an excessive price for low su hur and phosphorus scrap; (b) a sh -down until proper scrap can be ob- ta ed; or (c) bad castings and a dis- sa sfied customer.

Let us assume that the above situa- tic can be satisfactorily met. There is st the subject of requiring a low sul- phur for special occasions, as for in- stance, the making of a specially difficult casting where the foundry has its own particular difficulties and where a low sulphur steel would be of particular value in helping out the foundry. This can only be done in basic furnace.

Reasons 3 and 4 Acid and Basic

It is much easier to control the car- bon, silicon and manganese in the basic furnace, which means that where speci- fications have to be met the rejections are much less, particularly on physical tests, such as a good relation between the maximum stress and yield point, and a good elongation with a relatively high maximum stress. This is because of the inherent value of an electric furnace for making refined steels of a quality better than the converter steel, the open hearth steel and at least equal to crucible qual- ity, which is only present in the basic operation. Refining can be done in the acid furnace to a limited extent, but calls for skilful operation and is not re- liable.

Reason 5 Acid

The acid operation gives a better power consumption in the relation of about 100 to 112, because there is prac- tically no refining in the acid operation. It also gives a less refractory cost, as the cost of raw material is less and the repairs are less frequent.

"If alloy steels are ever contemplated a basic furnace is required. Manganese steels, for instance, so often required in the steel foundry industry, can only be economically made in the basic furnace. The use of other elements, particularly chromium, vanadium, etc., can only be handled in the basic furnace, and while the making of alloy steel castings may not be of immediate consideration their use is becoming more general every day, especially for parts requiring uniform wearing qualities, resistance to shock and resistance to alternating stresses.

Reason 6 Basic

A basic furnace invariably has a steadier load than an acid furnace, for two reasons: (a) Higher secondary voltages are used in the acid to bring about more rapid melting. (b) The re- sistance of an acid slag is higher than the resistance of a basic slag, and there- fore also requires a higher voltage.

Both of these calling for a higher sec- ondary voltage causes in practice longer arcs and higher surges because the elec- trode travel cannot pick up as rapidly.

Reason 6 Acid

In making all small steel castings three important points must be kept in view: (a) Do not have the furnace of too large a capacity—instal smaller units and more of them; for instance, when the castings do not exceed 10 to 15 lbs. a 1-ton furnace should be the maximum. (b) "Hot metal is essen- tial," because of the necessity of pour- ing into shank ladles where the transfer losses and the ladle losses are high and because of the number of "pours" re- quired. (c) It must be easy to hold back the slag and acid slag will keep back and separate more readily than basic slag.

This does not mean that small cast- ings cannot be made in the basic fur- nace, but means that in foundries where castings weighing ounces and a maxi- mum of say 25 lbs. are to be made, the acid operation is easier and more econ- omical.

Reason 7 Basic

Probably the latest field which is making very rapid strides for the elec- tric furnace in the foundry is for the refining of cast iron. This is particu- larly applicable to the making of engine cylinders, high pressure valves, piston rings and parts requiring uniform wear- ing qualities, etc., and the practice now being adopted is to pass the molten pig- iron from the cupola through the electric furnace for a refining period of 20 to 40 minutes, which gives: (a) a rapid desulphurization; (a) elimination of oc- cluded gases; (c) an accurate pouring temperature.

These causes will speak for them- selves to the progressive foundryman, who in the past on particular work had gone through periods of worry in his: Sulphur in the coke; blowholes, and "hot" metal and "cold" metal. Only the basic furnace can be considered for this purpose.

In looking over the number of fur- naces recently installed in foundries it must be surprising to the prospective buyer to find the large percentage of acid installations. This should not be taken as a criterion. These furnaces were only too often installed by foun- dries that used electricity as a "fuel" and the electric furnace as the melting pot, thereby hurting the electric steel field. They sold their product during a time when there was a loud cry for steel castings and when inspection was either entirely missing or at least lenient. The sulphur and phosphorus specifications were eased off and physical requirements were seldom met. This does not mean that the acid furnace had not its own field, as there are many cases where the correct "business" decision should be for the acid furnace, but this decision should be reached after a careful study of all the existing conditions and as many of the future conditions as possible.

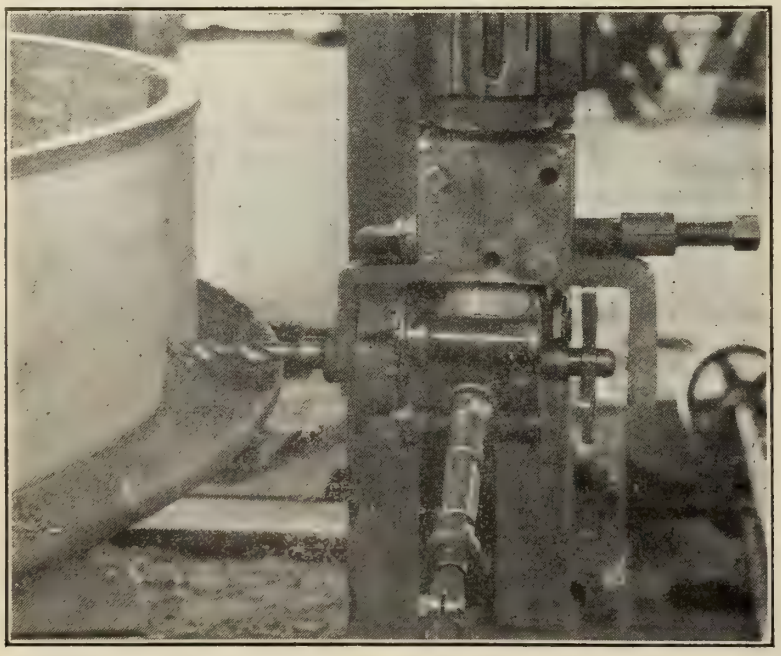
WHAT OUR READERS THINK AND DO

BORING HORIZONTAL HOLES ON A VERTICAL BORING MILL.

By F. A. McLEAN.

It sometimes happens in shops doing a wide variety of repair work, that a piece will come in for drilling that is too large to be handled on any post or radial drill in the plant. Such jobs are always a problem the successful solution of which, usually depends on the ingenuity and skill of the foreman in rigging up or adapting such tools and odds and ends as may happen to be at hand.

A case in point, which clearly illustrates the value of pneumatic tools for such work, is shown in the photograph. The brake ring on a large Corliss driven coal mine hoist was broken in service so badly that a new one was required. The casting for this ring or spider was between 9 and 10 ft. in diameter and had to be bored and turned all over. This was done on a 14 ft. boring mill and the next step was to drill 96 13/16" holes through the rim (which was about 1½" thick) to permit the bolting on, of wooden friction pads or shoes.



Owing to the large size and awkward shape of the ring casting, it was impossible to drill it on an ordinary drill press so that it became necessary to seek some other way of doing the work. The old method of doing a job of this kind would have been to use hand rachet drills, and figuring on about twenty minutes per hole and adding the time lost in shifting the drill, setting up the "old man," etc., would have probably required the services of two men for about 32 hours.

Drilling the casting on the floor with a pneumatic drill would require the services of two men for 8 hours and in addition some time would have been lost in shifting the casting from the mill to the floor and vice versa. After the friction pads were bolted in place they had to be turned to form a good seat for the brake band and it was finally decided that the best way of doing the job was to drill it on the boring mill, thus saving the time which would otherwise be lost in moving the piece to and from the mill and resetting.

A small pneumatic drill was clamped to one of the tool heads of the boring mill by a simple yoke as shown. The cross and vertical movements of the tool head were used for feeding and adjusting the drill up and down, while the table was revolved from time to time, as required thus acting as a sort of indexing device ensuring the proper location and alignment of the holes.

The actual drilling time, using the equipment illustrated, was eight hours for one man. The holes were all drilled true, very little time was consumed in shifting the drill. One and one-half hours was saved in moving the casting to and from the mill and half an hour for resetting piece to turn brake pads after they were bolted on, thus saving approximately twelve hours over the estimated time required for two men to drill this piece on the floor with a pneumatic drill.

It is obvious that the equipment shown could be adopted to boring large horizontal holes by using a portable boring bar suitably geared to the pneumatic drill chuck instead of an ordinary twist drill. Such an arrangement would be of value in repair shops not equipped with a horizontal boring mill or where it is desirable to have both vertical and horizontal holes bored in large pieces at one setting.

Method of clamping the drill to the boring mill so as to take advantage of vertical and cross feeds.

EMERGENCY HINTS

In the April 21 issue of Canadian Machinery we published an article on "Emergency Hints" by A. L. Marshall. The manner in which we published the material was rather confusing and as Mr. Marshall has pointed out to us the man we described had a lathe with large number of change gears, the meaning of course, that if he was a real mechanic he should be able to compound and cut almost any desired thread.

The meaning we intended to convey for Mr. Marshall was that the more modern lathe with its gear box arrangement with sliding gears and shift levers with the one having a tendency to stick the man on the job as there is no chance to change anything in an emergency.

We said in this article "Suppose the lathe you are using has a feed screw 5 inch pitch," this is wrong. It should read, "Suppose the lathe you are using has a feed which is gear driven with a ratio of 1 to 5 of the lead screw; when your lead screw is cutting leads for 1 inch your feed rod is giving one thirtieth inch feed per spindle revolution." There are plenty of modern lathes marked feed 5 times threads per inch or 3½ times threads per inch, etc.

Personality In Industry

IN the opinion of Professor Walter J. Matherly "Personality is the centre of all industrial values." While discussing the matter in a recent issue of Industrial Management he brings out many points of decided value, a few of which we reproduce. In his opinion Personality, whether within or without industry, is the "ego" in man. It is that which makes him different from other men. It is not that which he pretends to be but that which he is. It is the outward expression of his inward self. It is the man himself.

Personality, as found in industrial plants, is of many types. These are the weak personalities. These are the ones that are vacillating, who possess no ambition, no desire to climb up, no enthusiasm. There are the strong personalities. These are the men who are energetic, forceful, efficient, intensely interested; the men who hold responsible positions; the men who do things. There are disagreeable personalities. These are the individuals who rub us the wrong way. They are the obnoxious folk whom we may classify as the egotists, the autocrats, the wheedlers, and the distrusters.

Personality of the strong and forceful variety is the greatest asset in industry. While it may not be shown in annual balance sheet, yet it is certainly reflected in company earnings and in the efficiency with which products are put on the market. Personality is the energizing power in industrial organization. It enables executives to permeate every departmental activity and to get others to respect and carry out their program of activity.

Personality is a pre-eminent factor in salesmanship. Success cannot be attained in vending goods unless a man has force of character. A sales representative can not convince his customers of the superior qualities of his wares, and get orders wherever he goes unless he possesses an abundance of personal magnetism. Personality helps an individual to secure a job. It helps him to hold it. It gives him power to outgrow it and to reach up for higher jobs. It, coupled with brains and hard work, endows him with the capacity to scale the utmost business heights.

To develop personality, several qualities are necessary. The foundation is a resolute and disciplined will. Without will-power a man is crippled from the very beginning. Closely associated with will power is self-control. That is the second essential. Without the mastery of self, the mastery of industrial enterprise is an empty dream. The next element is self-confidence. An individual might be able to control himself, and even have the will to do, yet lack faith in his ability to carry out his plans. Another quality which is imperative is a mind eager to know and understand. It is impossible to get very far without knowledge. Unless human beings understand what they learn, they flounder about in darkness.

As a crown to personality, courtesy is needed. That means interest in others, thoughtfulness as to the welfare of others. It means looking at things through the other fellow's eyes. It means agreeableness, affability.

Personality, made up of such qualities, plays the leading rôle in present-day business. Without large-caliber men with personal force, warmth and ability, the whole industrial structure would crumble and fall.

Selecting New Equipment

SPEAKING on the subject of "The Selection of New Equipment" a writer in "Factory" tells of a plan whereby new equipment and machinery is purchased on the recommendation of committees, instead of relying upon the opinions of a single individual, or the buyer alone.

In using this plan, the factory manager appoints a committee from among the superintendents and foremen in whose departments the new equipment is to be used, and, in many cases, the workmen who will use the machines are included on the committee.

It is not the function of the committee to make final decision on the particular machine or equipment to be purchased. They merely investigate and consider the merits and disadvantages of the various machines that may be used, and recommend to the management the machine which seems most adaptable to the particular requirements of the factory as a whole.

This may seem like overriding the responsibility of the purchasing agent, but such is not the case. Actual experience with the plan proves that the plant using such a plan is more likely to be equipped with the most efficient machinery, at an ultimate saving in dollars and cents.

The following incident will show the advantage of the system:

A large factory in New York had found, by trying out various material-handling devices, that the lift truck with its interchangeable platforms was best adapted to one part of its work which was handled through several departments. A large number of these trucks would be required to handle this work, and as it was the policy of the firm to standardize on a single make of equipment, where possible, to cut down the number of different repair parts to be held in stock and also to facilitate the handling of the repair work, the question to be decided was which make of lift truck to use.

The factory manager selected a committee from among the superintendents and foremen who would use the trucks in their departments. The purchasing agent was at the same time instructed to invite each lift truck manufacturer to send one of his standard trucks for a trial period and to submit his prices on the quality which would be needed.

The manufacturers were glad to submit trucks for trial. The salesmen were informed that they were not to interview members of the committee during the trial period, and that they were to call only on the purchasing agent. Each truck in turn, was to be used in each department for a certain period, and the members of the committee were to study the trucks in service. Each foreman was to make a report on every truck.

At the conclusion of the trial period a meeting was held, and the committee discussed in detail the performance of each truck. Some of the points which seemed advantageous to one department were not so acceptable to another department and the committee had to trash out which points were most advantageous to the factory as a whole. In some cases a slight change in conditions in a department turned disadvantage into an advantage. Since that time experience has proved the committee's choice of truck an ideal one.

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

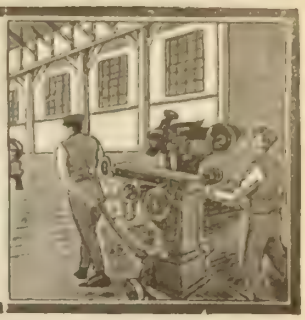
We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Elmore L. May, 2117 Dime Bank Bldg., Detroit, Michigan, was the only reader to submit a correct list in the July 28th contest. A scale has been forwarded to him. Again we request that any reader who does not receive his scale one week from publication of his name as winner, write us so that we may trace the matter up.

CONTEST FOR AUGUST 18TH ISSUE

Contestants are required to write us, stating to which advertisements we refer in this number.

1 What to do if you want the "newest."
2 - A case where there is a size for every purpose.
3 What a superintendent said.
4 An opportunity that should not be passed up.
5.—Something that somebody is willing to undertake.
6. How to keep a certain kind of bill down.
7 Something said to have set a new standard.
8 -A case where only one thing is made.
9—A product that is shipped promptly.
10 How to effect big economies.
11 --Something gathered from all civilized countries.
12—The value of a continuous hand chain guide.



These are Correct Answers for List from July 28th Issue:

1—Pratt & Whitney Co. of Canada, Ltd.
2—L. S. Starrett Co.
3—Dodge Mfg. Co.
4—John T. Hepburn, Ltd.
5—Canadian Blower & Forge Co.
6—Rockford Lathe & Drill Co.
7—Cleveland Pneumatic Tool Co. of Canada.
8—The Carlyle Johnson Machine Co.
9—National Electro Products, Ltd.
10—Northern Electric Co., Ltd.
11—Roelofson Machine & Tool Co., Ltd.
12—Canadian Fairbanks Morse Co., Ltd.

Closing Date for This Contest is Sept. 8th

DEVELOPMENTS IN SHOP EQUIPMENT

LARGE BORING MILL.

William Sellers & Co., Inc., Philadelphia, Pa., have recently produced a boring mill for machining castings used in large hydro-electric power units. This mill measures 35 ft. between the uprights, and 18 ft. between the table top and the tool when the cross rail is in its highest position.

The bed of the machine alone weighs about 50 tons. To enable shipping, it is made in two pieces, one piece extending from one upright to the other, and the other piece being bolted and doweled to it and extending forward so as to provide a portion of the bearing for the table. The over-all dimensions of the assembled bed are 19 ft. 9 in. in width, 9 ft. in length and 2 ft. 8½ in. in depth.

The table is supported on two annular bearings on which it slides when the machine is running. These bearings are supplied with oil under pressure, a pump being provided for this purpose. The table, complete with the driving-gear ring and the center spindle, weighs about 40 tons, and is 19 ft. 10 in. in diameter and 2 ft. 3 in. thick. It is provided with radial T-slots for clamping bolts. It is made in two semicircular sections, securely bolted and keyed together. The driving-gear ring is a separate casting 16 ft. 2½ in. in diameter, centered and bolted on the table. The table is provided with a large taper spindle 20 in. in diameter and extending vertically through the bed. A split bushing fits into the central hole in the bed, and is used for adjustment.

The spindle bearing is lubricated by the return oil from the inside annular bearing. The uprights are very heavy box castings 24 ft. 8 in. high and 12 ft. deep, the faces being 24 in. wide. They are bolted and doweled to the upper portion of the bed and the upper ends are tied together by a cast-iron cross-girt of heavy box construction. The cross-girt carries the lifting and traverse machinery drives and is accessible to the operator by a ladder carried on the inside of one of the uprights. A wooden platform with safety guard rails is provided to enable the operator to pass safely from one side of the machine to the other at the top.

The machine is driven through a 5 h.p. adjustable-speed motor with a variation of 3 to 1, and a speed regulating mechanism with four gear changes, giving a total range of 0.19 to 6 revolutions of the table per minute. The gears are all of large proportion with cut teeth. One feature of the drive which is worthy of mention is the short length of the shafts which are used throughout, in order to eliminate, as far as possible, the shaft deflections which may cause chatter.

The feed mechanism for the power feed of the saddles along the crossrail, and for the tool bars in the saddles is located on the sides of machine, and a total feed range from 1/64 to 1½ in. per revolution of table is provided for.

DOUBLE SPINDLE GRINDER

The Chas. H. Besby & Co., Chicago, Ill., have developed and marketed a new heavy pattern motor driven double spindle grinder. This machine is to be known as type I, and is suitable for wet or dry grinding. It is equipped with two 7½ h.p. a.c. special grinder type fully enclosed motors, and the starting apparatus is of the push button control type. The starters are attached direct to motor frame and are mounted in a sheet metal dust-proof case equipped with a hinged door. The motors are fitted with specially designed end casings and extra large and long ring oiling bearings. These motors are mounted on a bed plate and the two inner end casings or bearing supports have a footing on same which is machined on a perfect plane with the motor feet thus insuring rigidity right up to the nose of the spindle.

Motors can be moved along the bed of machine base to accommodate different widths of work to be ground. This movement is accomplished by means of racks and pinions. The motors are only moved on bed when it is necessary to change the machine from one width of work to another as both spindles themselves slide endwise through the bearings, feeding the wheels to the work being ground. This spindle movement is obtained through racks and pinions to which both hand and foot lever are attached. The movement is actuated on both spindles through a connecting rod attached to lever at the rear of machine. When desired, the connecting rod can be disconnected and the right hand spindle locked in a stationary position while the left hand spindle can be operated to and from the work through foot lever movement.

A pull spring is attached to a lever at the rear of machine, which is drawn out when spindles are moved forward to the work so that when the foot or hand lever is released this spring returns the spindles to their original starting position. Endwise movement is controlled by micrometer stop screws attached to each of the outer bearings. When the wheels are brought up to the work and a piece has been ground to the required depth the micrometer screws are set so that they come in contact with the bearing head casing, making a positive stop to the endwise movement of spindle.

The bearings are extra heavy phosphor bronze castings, the thrust being taken on a flange of large area. This flange is equipped with a hardened steel thrust collar and the thrust bearing is automatically oiled from the ring oiling bearings themselves. The oil reservoirs are extra large and the oil rings are of large diameter, which practically makes a flood of lubrication to all bearing parts. All bearings are dust-proof.

CYLINDER GRINDING MACHINE.

The Landis Tool Co., Waynesboro, Pa., have marketed a cylinder grinding machine especially designed for regrinding automobile cylinders. The range of work capacity includes all makes and types of automobile cylinders cast en bloc as well as a miscellaneous variety of irregular castings.

The grinding wheel spindle center of rotation is 10" above the top of the work carriage so that large castings may be easily handled with no extra or special fixtures. The grinding wheel spindle regularly furnished, will grind 15" deep and two wheels 2½ and 3½ inches in diameter are included as regular equipment. Eccentric adjustment of the spindle range from 1/16" to 1-1/16" which permits grinding holes as large as 5⅝" with standard 3½ diameter wheels. Two spindle driving pulleys are furnished to give correct peripheral speed of approximately 6,500 feet per minute with 3½" and 4½" diameter grinding wheels. Extra wheel spindles and sleeves for grinding 20" and 22" deep or for diameters larger than 6" can be furnished if necessary. These sleeves are interchangeable on the regular machine.

The work carrying fixture is an open angle plate design with two adjustable

work clamping bars. The work to be ground is securely clamped to the bars by two heavy machine clamps of ample capacity. A distinctive feature of this fixture is the arrangement for quickly and accurately aligning the work in vertical position to the center of spindle rotation. The entering bar fits into two slots milled in the frame of the work carrying fixture and carries two adjustable bearing brackets. Before clamping the work on to the machine these centering brackets are inserted into the hole to be ground to ascertain the exact size. They are set to this dimension and work is then lifted to the machine and fitted over the brackets of the aligning bar, where it is securely clamped to the work carrying fixture. After it is securely clamped in position this aligning bar is removed. If work is not absolutely aligned, minor adjustment can be made by a screw in front of the fixture which permits it to be raised or lowered as required.

The machine is arranged for either direct motor drive or for lineshaft drive through a small overhead counter. If motor drive is used a three horse-power motor operating at 1,150 R.P.M. furnishes ample power. If driving from counter a 3½" belt is used. Floor space occupied is 88 inches by 88 inches and net weight of the machine is approximately 2,900 pounds.

TRUS-FORM SNAP GAUGES

The Pratt and Whitney Co. Hartford, Conn., have recently added to their line of adjustable limit gauges, known by the name "Trus-Form." These gauges are constructed along the same general lines as a roof truss with the metal placed where it affords maximum rigidity. This frame of triangular cells has the flanges and ribs in tension or compression, forming a light and stiff construction. The outer rib with its broken lines affords a sure grip for the fingers, even when they are oily. A unique adjustment is provided for the anvils in the following manner:

Two opposed screws pull in opposite directions like the screws of an independent lathe chuck, and by pulling one against the other the finest adjustment is easily made, this adjustment being positive in either direction. When both screws are tight, the anvil is securely locked against shake in any direction. It cannot be jarred loose and may readily be sealed. The holes in which the anvils work are accurately line-reamed, and the anvil faces are lapped square before assembling.

New anvils can be substituted at any time, these being interchangeable. In all sizes over ½ inch, the anvils have heads which permit of gauging to within 1/32 inch of a shoulder. In the smallest size, as an extra, two special anvils with offset heads may be used in the "Go" position, where it is necessary to work close to a shoulder. These are not needed in the "Not Go" positions.

When necessary to mark sizes, tool numbers, operation numbers, etc., two pairs of brass buttons are secured by special screws. They are readily removed to a bench plate for stamping, and they may be filed off and re-marked. One pair may be used for any permanent marking and secured by riveting over or soldering the point of the screw. These gauges are made to cover a range from 0 to 12 inches in fifteen different sizes, as follows: 0 to ½, ½ to 1, 1 to 1½, 1½ to 2, 2 to 2¾, 2¾ to 3½, 3½ to 4¼, 4¼ to 5, 5 to 6, 6 to 7, 7 to 8, 8 to 9, 9 to 10, 10 to 11, and 11 to 12 inches.

GEARED HEAD LATHES

The Morris Machine Tool Co., Cincinnati, Ohio, have placed on the market a line of geared head engine lathes, these being in 16 in., 18 in., and 22 in. sizes. These machines have a single pulley drive, are geared in the head, and provide twelve spindle speeds. With a double friction countershaft twenty-four speeds or twelve forward and twelve reverse are obtained. All the gears are of steel, heat treated and hardened. The headstock is filled with oil up to a certain level, permitting the gears to dip enough to thoroughly lubricate them.

All speeds are secured through one front gear and one positive back gear clutch, friction clutches or any parts requiring adjustment having been eliminated. The only friction clutch is in the pulley at the initial drive, which is of a large diameter and is controlled by a shifter rod running the full length of the lathe. This permits the operator to start and stop the lathe from any working position. Speed changes are secured through the levers in front of the head, the two levers at the back end controlling a set of sliding gears giving six speeds. This lever, when engaging the direct drive clutch, slides the back gear pinion out of mesh, preventing the back gears running idle at high speed and from absorbing unnecessary power. Pulley is protected by a guard which can be swiveled to suit the angle of the belt.

The geared heads are interchangeable with the cone head. All geared heads are arranged to receive the motor drive unit at any time. The motor is mounted on a plate, bolted to the head and drives the clutch pulley by an endless belt which is furnished with the motor drive details. An idler pulley adjusts the tension of the belt by means of the sta handle at the front of the motor plate The idler pulley and bracket are mounted on the motor plate, making the moto drive unit self-contained.

When releasing the friction clutch i the pulley, a brake can be applied b the same pull which stops the idle rota tion of the spindle. This is a grea convenience both when shifting gear and when turning work partly around fo inspection at different points on th diameter.

It Pays to Give Service

"CONSIDERABLE improvement is necessary in the quality of work coming from the foundry." Such an article as Mr. Hampson wrote in the July 21st issue of Canadian Machinery would be unnecessary if foundry owners would try to get the manufacturers' viewpoint, and there is no reason why this should not be easy of accomplishment. When a person goes into a store for an article, they do not like to pay out their hard-earned cash until they have been shown something of good quality. In other words they get what they want before purchase. The same condition should hold good in the foundry.

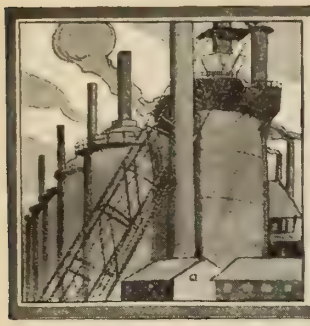
Why should a manufacturer pay for castings which are too hard to machine; too full of holes to be worth using; or as often happens, too warped to be of the slightest use? These conditions may seem far-fetched, but they are happening every day. A case came to our notice recently that is well worth repeating. It seems that this concern gave all their work to one particular foundry. This arrangement dated back to 1914, so that the foundry in question had no competition so far as this firm was concerned. A considerable volume of work yearly was turned out, and in this case the grade of castings received was very satisfactory—or rather was—until the recent war broke out.

Extensions were made to the foundry to handle extra work, for in those days one was lucky to even get work into a foundry. Imagine the surprise of the manufacturer when the foundry began sending very poor castings, so poor that they were unfit for use. Believing it to be an accident, he called the owner's attention to the bad batch, getting in return, a load of abuse. The manufacturer, realizing the scarcity of foundries which could handle his work swallowed his pride and disappeared. Thus, the first victory went to the foundry owner.

The second battle was short lived. Without warning, the manufacturer received all his patterns having intricate cores, with a note saying that from now on only simple core work would be handled. This left him strictly up against it, for without these castings his product could not be turned out. To make it worse the patterns were in very bad shape, thanks to rough treatment, and it took over a week to put them in good condition.

During this time a wild hunt was in progress to find a foundry that would handle his work. "Are the pieces solid or cored," used to be a favorite query of the foundry owners all on receiving his reply, the plea of rushed business, lack of good coremakers. etc., was given. Eventually a foundry was found which would handle the work and from all reports they did so at a lower rate than the first foundry making the castings, yet turned over a handsome profit, as the volume of work was considerable.

And now comes the punch of the story, as the author would put it. Today, the foundry owner that gave the manufacturer such shabby treatment is running wildly to and fro for business, when just a stonethrow from him is the concern whose work he turned down. Naturally he has tried to get the work again, but the manufacturer is luckily blessed with a good memory.



Of course this tale may be an extreme case, but in a milder form the same conditions existed all over the country during war time. Old customers were forgotten, new friends were made at high prices, but today the old reliables are in business while the new firms are a thing of the past. Foundry owners can still make good by showing they are anxious to serve the manufacturer. There are quite a few foundries in existence today which know the meaning of real service. Let them be an example to those who merely think of the tonnage passing through their shops. When foundry owners co-operate with factory executives, giving them castings to suit their particular requirements, the biggest step in the right direction will have been taken.

Preparing Goods For Export

SOME good advice for exporters is given in an article appearing in another portion of the present issue. The author, who is trade commissioner at Melbourne, says that new cases should always be used for export, also that tongue and grooved lumber is especially desirable for the packing of high class and expensive goods. He points out that the cases should not be too large; that the parts should be so packed that they do not shift; and that the cases should be lined with some sort of paper or cloth to exclude the effects of the sea air and other moisture in transit.

Canadian Machinery has always been a staunch supporter of careful packing, both for home and export shipping. From time to time articles have been published showing methods which have been found successful, and these stories, together with similar articles published by other technical journals have had their effect. At the present time the larger firms having export business have set aside a separate staff of men whose duty it is to prepare export boxes. One large concern in the United States has everything reduced to such a point that the boxes for their various products are cut according to blue print. Several Canadian concerns that we know of also follow out the same practice, although on a somewhat smaller scale.

There is no question about the rough handling such packages receive. Anyone who has watched the loading of a ship knows how the dock hands reverence the sign "Handle With Care." While it does no harm to mark boxes in this way the safest form of protection is to make them in such a manner that they cannot help but be handled properly. Wherever possible, embody as part of the box, the eye through which the slinging hook will go. This will ensure the box being lifted and kept right side up. Rules for marking should be carefully observed, for many a box has been delayed through this cause. Consider every step of the journey; place yourself in the position of the package, then put on it the protection you would ask for in order to arrive in good condition yourself, always provided of course you were made of similar material to the goods being shipped. Place your best men in the export shipping department, men with visionary power, and above all see that your checkers are fully alive to the responsibility of their position. Let them understand that a satisfied buyer means not only repeat orders, but possibly an established trading connection.

MARKET DEVELOPMENTS

So Far This Month Market Shows Improvement

July was a Poor Month for the Steel Mills—Output Has Since Improved and by November it is Expected that Further Gains Will Be Made—Pig Iron Moves Slowly.

THE July market was a poor one for steel mills and it is questionable if any other will show such a low average. About the middle of the month an improvement was noted. Since that time the market has improved slowly but surely, and a further improvement is looked for as time goes on.

The steel ingot output in July was about 11,000,000 gross tons a year, or about equal to 21 per cent. of capacity. The low point in output fell at about the middle of the month. So far this present month a little gain has been reported. A 35 to 40 per cent. rate is looked for by November. This would mean more than double what the mills were producing a month ago.

The increased demand upon the mills is said not to be a reflection of business being more active generally, but of people buying more in relation to the general volume of industrial activity. Business in the United States is more active than it is given credit for. The improvement shown is not only likely to be held but should improve week by week.

The bottom seems to have been reached so far as steel price are concerned. Practically all the decline has occurred, an until freight rates, wages, and such important determinin factors drop, prices in steel are fairly sure to hold. Pig iro shows some signs of activity although the movement is ver slight.

Machine tools are not much in demand these days. Produc tion tools are not moving at all, and even re-built tools are nc being enquired after. Manufacturers seem to be holding tigh spending as little as they possibly can.

Small tools are not moving very rapidly, although in som lines the prices are said to be down to 1913 levels. There are n changes in price from last week.

No. 28 gauge galvanized sheets are selling at $7; No. 2 black at $6; while No. 10 gauge blue annealed is selling a $4.50. Bar and bar mill material shows no change, selling a the old price of $3.75 base.

BUSINESS IN UNITED STATES IS MORE ACTIVE THAN IT IS GIVEN CREDIT FOR

Special to CANADIAN MACHINERY.

PITTSBURGH, August 18.——The monthly report of the American Iron and Steel Company, giving the steel ingot production of 30 leading companies, permits an accurate estimate to be made of the production by the whole industry in July, a month that will probably never be equaled in future for lowness of production. As indicated by these market letters in recent weeks, it was the month in which the turning point occurred as to the volume of demand upon the steel mills.

The steel ingot output in July was at the average rate of about 11,000,000 gross tons a year, equal to about 21 per cent of capacity, this being made up of an operation of about 5 per cent by the United States Steel Corporation, and about 18 per cent. by the independents, taking the independents as a whole. The low point in output fell at about the middle of the month, when the industry probably operated at between 18 and 19 per cent. At both the beginning and end of the month the operation was heavier, and there has been a little gain thus far this month, so that the rate now is probably about 25 per cent. of capacity. A 35 or 40 per cent. rate may easily be reached by November. While a 40 per cent. rate might not seem like much it would mean more than double the mills were producing a month ago.

In some uninformed quarters reference has been made to the Steel Corporation's showing of unfilled tonnage decreasing 287,544 tons during July as being a favorable indication, because in preceding months the decreases had been larger, tapering off from the 649,102-ton decrease reported for last March. It may be well to state specifically that the smallness of the decrease, in the circumstances, is unfavorable, although the facts were already so well known that it does not make any difference. In the five months March to July inclusive, the Steel Corporation was engaged almost wholly in filling shipping orders or specifications furnished by customers against their contracts, made long ago. The "unfilled tonnage" reported monthly includes all such contract tonnage. The more the customers specified, the more the corporation shipped, the more money it made and the more the unfilled tonnage decreased. Shipments in March were at about 51 per cent. of capacity, the decrease in unfilled obligations for the month being 649,102 tons. Shipments in July were at about 25 per cent of capacity and the u filled obligations decreased by 287,5 tons. In each of the five months the co poration booked a little new tonnage, a eraging about 100,000 tons a month. Th when there is a little new buying a lar decrease is favorable, showing that cu tomers are willing to take steel. Of cour it would be still beter if they took all steel ordered and bought more still, which case there would be an increa in the unfilled obligations. The corpor tion does not need to make new sales this time, its interest being in having i customers take tonnage already contrac ed for. The independents are in a di ferent position. Having had prices 1920 much above those of the Steel Co poration, they have little contract tonna now, and their business is chiefly in ma ing fresh sales.

Demand Increasing

Week by week for five successi weeks there has been basis for repo ing an improvement in the demand u on the steel mills, and it might thought that by this time there is qu a demand or, if there is not, that t improvement has been just talk. Nei er has been the case. There has be continuous improvement, but it has be at a very slow pace, and there is a lo road to travel because at one time th was hardly any demand, or the m would not have been operating at l

than 20 per cent. of capacity. It is undoubtedly. a case of "slow but sure" The increased buying and specifying is not attributable to "sentiment" or "an improved tone" or "more optimism" the hackneyed expressions that are so often used, or misused, in market reporting. There is no sentiment at all about this market. People are buying because their stocks have run out or become ragged, when previously they had been drawing upon stocks or had been distributing machinery, implements, tools, etc., previously manufactured.

The demand upon the steel mills had been far below the actual ultimate consumption for many weeks and with the gradual reduction in stocks the demand is working up towards a normal relation. The increased demand upon the mills is not a reflection of business being more active generally, but of people buying more in relation to the general volume of industrial activity. The fact is that general business in the United States is much more active than it is being given credit for. There has been talk about several million people being out of employment, but there are about 45,000,000 altogether who are either working or want to work. The freight ton-mileage on the railroads was at a greater rate in May than in April, and was at a rate slightly greater than the rate in the best railroad year before the war, the year ended June 30. 1913. Debits to individual accounts at banks, reported by the Federal Reserve Board as an indicator of the volume of the nation's business, have been lagging only 14 to 17 per cent. behind those of a year ago. Demand upon the steel mills has been below a normal relation , and as that could not continue for any length of time the improvement now being experienced is certain to be held, while further improvement in future is certain.

Steel Prices Steadier

For months buyers have been looking for lower and lower steel prices, and properly, but the point now is to know when to stop looking. Very nearly all, and perhaps all, of the decline has now occurred. Prices cannot of course return to the pre-war level, with freights involved in iron and steel making up 75 to 100 per cent. and wages up 50 per cent. or more, taxes perhaps doubled, and various other things all higher. Should freight rates come down 20 per cent. a few months hence, and that is about all that could be expected, they would still be up about 50 per cent. Wages are likely to average about 50 per cent. advance for some time if not for years. There is to plain showing by comparisons that steel prices are now relatively low, and there is the showing of the actual market, that in the past week there has not been a single definite decline. Prices are more or less irregular, some mills quoting a little lower than others, and slightly lower prices being quoted on the more desirable orders than on the less desirable orders, but the shading on the whole is little greater than a week or two ago, and in bars, shapes and plates there is some question whether concessions from regular prices, on especially desirable orders, are altogether as great as two weeks ago. The "regular" prices are $.75 on bars and $1.85 on shapes and plates.

Pig Iron

Pig iron in the past week has been showing possibilities of there being a turn. While there remain ample stocks of basic on this market, stocks of foundry and Bessemer seem to be small, and two or three sellers of foundry iron state they have withdrawn from the market. This means that what little stock they have left they wish to keep to feed out to regular customers. In the Cleveland and Buffalo districts there are still fairly large stocks. Prices in the valley market are unchanged, at $20 for Bessemer, $18 for basic and $19.50 for foundry.

POINTS IN WEEK'S MARKETING NOTES

The month of July will probably never be equalled in future for lowness of production. However it proved to be the month in which the turning point occurred, for the demand on the steel mills has slightly increased since the middle of July.

For the past five weeks an improvement has been noted in the steel market. This movement has been continuous, but very slow which accounts for some doubting even its very existence. It seems to be a case of "Slow But Sure."

Sentiment does not exist on the market. Where buying occurs it is because the stocks have run out entirely, or at least become very ragged.

General business in the United States is not so poor as some would have us believe, according to reports received from our Pittsburgh correspondent.

It would seem that the point is being reached where people must stop looking for lower prices. Dealers feel that nearly all the decline has occurred. They say that prices cannot possibly return to pre-war level so long as freight charges remain as high as they are at present high wages, taxes, etc. being other considerations.

Pig iron during the past week has been showing possibilities of an increase in demand. There still remains ample stocks of basic on the market while stocks of foundry and Bessemer seem to be small. Prices remain unchanged.

The machine tool market remains in a sort of comatose condition. Nobody seems to be wanting anything. Enquiries do come in occasionally, but at present they go no further than enquiries. A spirit of optimism is making itself felt however and improvement is looked for although the process will be gradual. The same can be said about small tools.

Scrap iron remains in exactly the same position as last week. The demand is very light, the prices quoted are as low as they are expected to go and on top of that nobody is hurrying to buy.

Pig Iron Output

In the Dominion Bureau of Statistics report, it is stated that the advance in the output of pig iron ferro-alloys in Canada, noted in the May report, was fairly well maintained during the month of June. Pig Iron production declined slightly from 56,091 long tons to 54, 812 tion, but the amount of basic iron made rose from 44,002 long tons to 48,870 tons, all of which was used by the makers. The output of foundry iron made for direct sale dropped slightly from 4,709 tons in May to 4,389 tons in the month under review. Foundry iron produced by makers for their own further use, showed a considerable decrease from 5,206 tons in May to only 825 tons in June, so that the total output of foundry iron declined from 9,915 tons in May to 5,214 tons in June. Malleable iron was also lower, dropping from 2,162 tons in May to 661 tons in the current month. Sixty-seven tons of iron castings was made from electrical furnaces. No other electric iron was produced during the month. A total of 717 tons of ferro-alloys was made during June, as compared with 944 tons during the preceding month.

Six blast furnaces were active at the end of June, one additional furnace having been blown in during the month, by the Dominion Steel Corporation at Sydney. At the close of the month, three furnaces were being operated at Sault Ste. Marie, one at Hamilton, and two at Sydney. During the six months ending June 309,206 long tons of pig iron was made in Canada, as compared with a total of 449,810 long tons during the same period in 1920. The output for the first six months of this year was, therefore, only about 69% of the amount made during the corresponding period of 1920. Of the pig iron made, 249,008 long tons was produced from blast furnaces by firms for their own use in further process of manufacture; 59, 897 tons made in blast furnaces was produced for direct sale. Of the 301 tons of electric iron made during the period, 222 tons was made for use and 79 tons of iron castings was made for sale as such. An analysis of the pig iron output for the six months ending June shows that 71% of the total was basic iron; 21% foundry iron, and 8% malleable iron. Coke was the only fuel used in the manufacture of pig iron in Canada during the period. The production of ferro-alloys, including the several grades of ferro-silicon, and also spiegeleisen, amounted to 10,781 tons during the half year.

DEMAND IS VERY LIGHT AT PRESENT IN TORONTO—MACHINE TOOLS DULL

Special to CANADIAN MACHINERY.

TORONTO—The summer season is still making itself felt on the Toronto market. The various dealers spoken to by Canadian Machinery say that little change has occurred since last week. No large sales are being made, and although a few enquiries come in here and there, they seldom develop into real orders. When an order does arrive it is for a very small amount. One dealer stated that he had not sold a "Production" machine for a long time. By such a term he of course means to cover any type of machine tool that is specially adapted to speeding up production.

Re-built tools are also moving very slowly. It would seem as if manufacturers had decided to do absolutely nothing for the present. If they are waiting for still lower prices, they are waiting in vain, said one dealer, because prices have dropped as low as they can. When one compares present prices with the high freight rates, high wages, etc., he continued, they can readily see why we can't drop further until the various factors controlling these prices drop accordingly.

One dealer claims that in some lines the prices are down almost to 1913 levels. This is said to be especially true in some lines of small tools. The latter commodity moves, but very slowly. There does not seem to be much demand for new tools, manufacturers using their old ones rather than spend money. The prices on small tools remain the same as last week. Speaking on future possibilities, one dealer said that he could see no reason why this section of the business should not pick up very shortly. Of course such a change would not be sudden, he continued, but would take the form of a gradual improvement.

The Steel Market

The steel market merely moves along these days, neither up nor down. Prices seem to have reached bottom, and while the demand at present is light, improvement is looked for shortly. No. 28 gauge galvanized sheets are now selling at $7 per 100 lbs. No. 26 gauge, black is at $6, while No. 10 gauge blue annealed sheets are selling at $4.50. Bars and bar mill material show no change, this material still selling at $3.75 base. The demand for boiler tubes remains light, and the prices on these are the same as last week.

Scrap metal is still the black sheep of the market. There is hardly any business at all and according to one dealer, not much improvement can be looked for at present. The market situation can readily be summed up in the words of one dealer who remarked that he had stopped guessing what was going to happen. One thing sure however, is that everyone feels the worst has been passed through, and from now on things must get better instead of worse.

Steel Ingots and Castings

The output of steel ingots and castings in Canada during the month of June was the highest for any month during the present calendar year, the output rising to 64,103 long tons, an increase of more than twelve thousand tons over the production for the previous month, which was 52,001 tons. Direct steel ingots accounted for 62,339 tons as compared with 50,068 tons during the preceding month, and of this quantity, 62,190 tons was basic open hearth steel produced by the makers for their own use. A total of 144 tons of electrical steel ingots was made, of which 139 tons was made for further use by the firms reporting. Basic open hearth steel castings were also a little higher for the month, the production being 389 tons, consisting of 100 tons made for further use and 289 tons made for sale. Steel castings made from electrical furnaces showed a slight decline from 1,738 tons in May to 1,278 tons in June, of which 1,164 tons was made for sale, and the balance was used by the producing firms.

The total production of steel ingots and direct steel castings during the six months ending June amounted to 295,140 long tons, of which 284,197 tons was produced for use in further processes of manufacturing by the makers; the balance, or 10,943 tons was made for sale. By far the greater amount of steel made was produced by the basic open hearth process, the total for this item amounting to 282,648 long tons, of which 280,839 tons was in the form of steel ingots and was used by the makers, and the balance, or 1,809 tons, in direct steel castings. Of this latter amount, 1,423 tons was made for sale, and 386 tons for the use of the producers. Electric steel production amounted to 10,938 tons of which 9,585 tons was produced as direct steel castings and 1,353 tons was in the form of ingots. Nearly eight thousand tons of the direct steel castings made from electric furnaces was marketed directly as finished product. Very little open hearth steel was made during the six months' period, the amounts recorded being 239 tons of ingots made for use, and 256 tons of direct steel castings, practically all of which was sold as such making a total of 495 tons in all. Converter steel production amounted to 1,059 tons, most of which was made for direct sale as steel castings.

The average monthly production of steel ingots and direct steel castings for the half-year ending June 30, 1921, amounted to slightly more than forty-nine thousand long tons, the total output for the period being 295,000 tons. During the same months in 1920, the average production was ninety-one thousand tons, and the total, 574,000 tons. The monthly average for the eight-year period, 1907 to 1914, inclusive, was sixty-two-and-one-half thousand tons, so that the June production this year is somewhat higher than the pre-war average.

FIRMS WANT GOODS

3245. **Agricultural Supplies.**—A London firm dealing with the Near East would like to be put in touch with Canadian suppliers of agricultural implements and machinery and other agricultural goods suitable for the Near Eastern markets.

3231. **Lanterns, Axes, Hammers, and Builders' Hardware.**—A London company who are buyers of hurricane lanterns, axes, hammers, and other tools, and general builders' hardware, are open to consider offers from Canadian manufacturers.

3232. **Hardware and Tools.**—A commission agent in London buying for clients in South Africa would be interested to receive regular quotations from Canadian exporters of picks, shovels iron and steel materials, and other Canadian requirements of the mining districts of South Africa.

3233. **Chemicals.**—A commission agent in London, England, buying for clients in South Africa, would be interested to receive quotations from Canadian exporters of caustic soda, cyanide of sodium, and other chemicals required for the mining districts of South Africa.

3229. **Cement.**—A Liverpool firm desire prices of the above, in casks of 40 pounds gross, for export to the Gold Coast, West Africa.

A SERIOUS ERROR

The advertising department have asked us to call readers' attention to a serious error which occurred on page 63 of the August 4 issue. On this page was an advertisement of the Norton Co. of Canada. Ltd. In italics it was stated that Norton Crystolon wheels were suitable for any work on steel or any other materials of high tensile strength. At the opposite side it was claimed that Norton Alundum wheels were good for any work on cast iron, brass, and other material of low tensile strength.

Of course to mechanical readers the error is self evident, viz, that the reverse is true. The Crystolon wheels are specially adapted for iron, brass, etc., while the Alundum wheels are best suited for steel work, and such high tensile materials. Considering the fact we are working with a staff of men who are not familiar with our work, we are having very few typographical errors.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

IT PAYS TO CONSIDER INTERESTS OF OVERSEAS BUYERS—RULES OF EXPORT

CANADIAN exporters should consider the interests of overseas buyers as their own." Trade commissioner D. H. Ross at Melbourne, is responsible for this truthful remark, and he goes on to say that a satisfied buyer means repeat orders and, probably, an established trading connection which may endure for a long period of years.

In many instances, he continues Australian buyers—especially of new lines—attach a packing sheet to their indent on which is clearly set out the contents of each case, besides requesting that iron hooping or wiring should be used in a specified manner. In ordinary lines of merchandise, the usual trade package to which the trade has become accustomed is implied as a matter of course, hence no specific packing instruction may be given. When oversea buyers give packing instructions, founded upon their long experience of their special requirements, it is absolutely essential, for the reputation of the Canadian suppliers, that careful compliance should be given to every detail outlined. Credit must be given to distant buyers as to their knowledge of what packing their particular trade requires, however inconsequuous the instructions may appear to the shippers. It it obvious that want of consideration in essential packing—and minor shipping details—reflects not only upon the delinquent manufacturers but also upon the methods of Canadian exporters as a whole.

Improvement in Packing

In recent years the packing of Canadian goods shipped to Australian markets has greatly improved, as manufacturers have taken an intelligent interest in following the instructions of overseas buyers in order that their goods should arrive in good condition. It is now the exception to receive complaints regarding Canadian packing.

In concluding his talk on packing for export, Mr. Ross says that certain factors enter into good practice. Following are the suggestions he makes:—

New cases should always be used for export.

The timber to be used depends on the contents of the package, hence no fixed recommendation can be made, for this is a matter to which the manufacturer's intelligence and desire to give satisfaction are commended. Tongued and grooved timber is desirable especially for high-class and expensive goods.

3. Cases should not be too large and should be closely packed to prevent the contents shifting en route. Waste space means additional expense to the oversea buyer besides adding to the landed cost of the goods.

4. Cases should be well lined with strong waterproof paper to avoid the effects of the sea air and other moisture in transit. The necessity of this essential lining of cases is more frequently ignored than followed by Canadian exporters. To the waterproof paper is recommended an additional inside lining of strong kraft or cartridge paper.

5. Zinc or tin-lined cases are often used by British and Continental shippers for special goods, and for this extra expenditure the buyer is charged. Buyers frequently stipulate such packing, but without a definate instruction shippers must use their own discretion always with the object in view of landing their goods in perfect condition.

6. Carefully check contents of cases before packing; two persons are recommended for this purpose.

7. In packing machines every part (screws, bolts, etc.) should be checked beyond the possibility of an error, for commissions are often unobtainable where the parts are unpacked.

8. Avoid straw or hay which absorbs moisture in packing fragile or light and bulky goods. The packing depends on the nature of the goods, but, generally, excelsior or wood wool and waste paper are preferable to vegetable materials.

9. Cases should be clearly stencilled with the marks of the oversea buyers, numbered, and the port of destination must be clearly indicated. Preferably, the marks on cases should be stencilled in indelible ink and in prominent characters. In some countries stencil marking is obligatory.

10. The cubic measurement (extreme outside dimensions) should be stencilled on each case (e.g. 30 inches by 20 inches by 18 inches) and noted on the invoice to facilitate landed costs being computed. The cases should be weighed, particularly after packing, and the gross weight stencilled thereon as a check (to a limited extent) against pilfering. The number and contents of each case should be clearly shown on the invoice.

11. Unless otherwise instructed, cases are always preferable to crates or bales. In loading or discharging ships, stevedores use cargo hooks (despite marks of warning) and the contents of bales are frequently damaged thereby.

12. An endeavour should be made to pack only one class of goods in each case.

13. Should catalogues, price lists, or advertising show cards, be enclosed in a case, it is necessary to state the weight of all such printed matter which is dutiable in Australia at the rate of 20 cents per pound. Failure to disclose such particulars on the invoice may, on examination by the customs, cause the importer to be substantially fined. Unless requested by buyers, it is inadvisable to enclose any extra printed matter.

RAILWAY IS NOW A PAYING PROPOSITION

Wonderful Results Since Henry Ford Has Taken Over The Railroad Between Detroit And Irontown

A short time ago Canadian Machinery acquainted its readers with the fact that Henry Ford, had taken over the Detroit, Toledo, and Irontown railway, and that he had decided to pay over the union scale, making the minimum rate $6.00 per day. The aftermath of the above reading notice is told by the Wall St. Journal which says that if every railroad had a shipper of Ford's capacity as godfather or owner, operating problems would become simple. They go on to say that he has sent over his rails sufficient traffic to turn a consistent deficit into an operating profit of more than $500,000 in the first six months of 1921.

He has also been able to cut two hours off the running time between Detroit and Bambridge, a distance of 280 miles, and the trip is now made in 10 hours with 28 scheduled stops. Most of the freight is moved at night, and by speeding up shipments Ford says he has cut the time when raw material leaves the manufacturer until finished automobiles reach the dealer from an average of 22 to 14 days. This in turn freed $22,000,000 in inventory for other purposes. Instead of a former record of 200 cars moved in 24 hours, the new road, or at least the new management have moved as many as 1,200 cars in the same period.

BRIDGE TO BE BUILT WILL JOIN PHILADELPHIA AND CAMDEN SOON

IN THE August 4 issue of Canadian Machinery we give some interesting figures on the proposed Hudson river bridge. Believing readers will be further interested in the new bridge which is to be built across the Delaware river, we append some of the interesting features in connection with it.

At the time of writing, work will no doubt have been started on this bridge which is of the two-cable suspension type. The bridge will span the Delaware between Philadelphia and Camden, a distance of 1,750 feet. The main span will be 1,750 feet. between towers with a clearance of 135 feet above high water. The two cables on which it will be hung are to be 30 inch diameter, being made up of 16,531 wires, .192 inch diameter. All parts of the bridge will be designed to safely withstand a live load of 11,990 pounds per lineal foot.

The span of the bridge will be 50 feet shorter than our own Quebec bridge, so that Canada still has the second largest bridge of its type in the world, the new Hudson of course, being the largest. It is estimated that about 33,000 tons of metal will be used, and the cost will be somewhere around $28,871,000.

Ralph Modjeski of Chicago, George S. Webster and Laurence A. Ball comprise the board of engineers which recommended the bridge, and six months was taken considering sites, etc., before the definite plans now arranged were settled.

In their report the engineers stated that they selected the suspension type of bridge because it involved less risk in construction, and would be considerably cheaper and quicker to build. They also touched upon the possibility of increasing the capacity of such a bridge as against the cantilever type, and also stated that there would be less exposed surface to paint on a suspension style bridge.

Traffic Arrangements

Six lines of traffic have been arranged, each line being 9 ft. 6 inches wide to take care of the largest trucks. The width from curb to curb on the main structure has been set at 57 feet. Room is also provided for two lines of tracks for a bridge shuttle service, and two more for an extension of the city's high speed transit lines over the bridge when such is desired.

The main piers are to be 380 feet high and 60 feet wide, and the wire used for the cables have an ultimate strength of 215,000 lbs. per square inch, and an elastic limit of over 144,000 lbs. per square inch.

Owing to local conditions it has been found advisable to carry the cables to an anchorage a considerable distance back of the towers. For economic reasons the side spans are suspended from them. The cables and towers necessary for the main span sustain the fixed load of the side spans with a very small increase in size and cost.

By placing the walkways on the upper lateral, and bracing and grouping the vehicle and car roadways on the lower levels, the designers have reduced considerably the width of deck space. The roadway is inside the carlines.

Rock suitable for foundations of the bridge was found at 86.7 ft. on the Philadelphia side and 91.6 ft. on the Camden side below mean high water at the side recommended by the engineers, while at other sites considered the rock level was near the practicable limit of pneumatic foundation work, exceeding on one side of the river or the other 110 ft., below which depth men could only work in half hour shifts. Although not of such huge proportions as the Hudson River bridge, this structure is a much needed one, and will relieve the present congested ferry service between these two points.

TONNAGE INCREASED DURING WAR PERIOD

Total is 11,000,000 Greater Than at First of July 1914

During the three years ending Dec. 31 1920, the tonnage of sea going merchant vessels comprised more than 25 per cent. of all similar tonnage launched in the twenty-nine years beginning with 1892, for which the compilations of Lloyd's Register of Shipping are available.

Prior to the European War, the largest amount of shipping launched in any year was 3,332,882 gross tons, in 1913. Ship construction decreased during the earlier phase of the war, falling to 1,201,630 tons in 1915. In the following years, however, urgent demand for tonnage stimulated construction, but it was not until 1918 that total launchings exceeded those of 1913. In that year, thanks very largely to the construction of more than 3,000,000 tons in the United States, the world's shipyards launched 5,447,444 tons, while in 1919 the total was 7,144,549, of which more than 4,000,000 were the product of American yards. In 1920 shipbuilding activity was reduced somewhat, but launchings were still in excess of any previous year except 1919.

In spite of the destruction by enemy action of over 13,000,000 gross tons of seagoing merchant vessels, between August 1, 1914 and November 11, 1918, and the loss through marine hazards of an additional 2,390,000 tons during the same period, the world's mercantile tonnage afloat is to-day greater than it would be had the average rate of increase for the ten years prior to 1914 continued in the years since that date. Estimates of tonnage now afloat indicate a total in excess of 60,000,000 gross tons, approximately 11,000,000 gross tons above the figure for June 30, 1914.

TRADE MARKS SHOULD BE REGISTERED

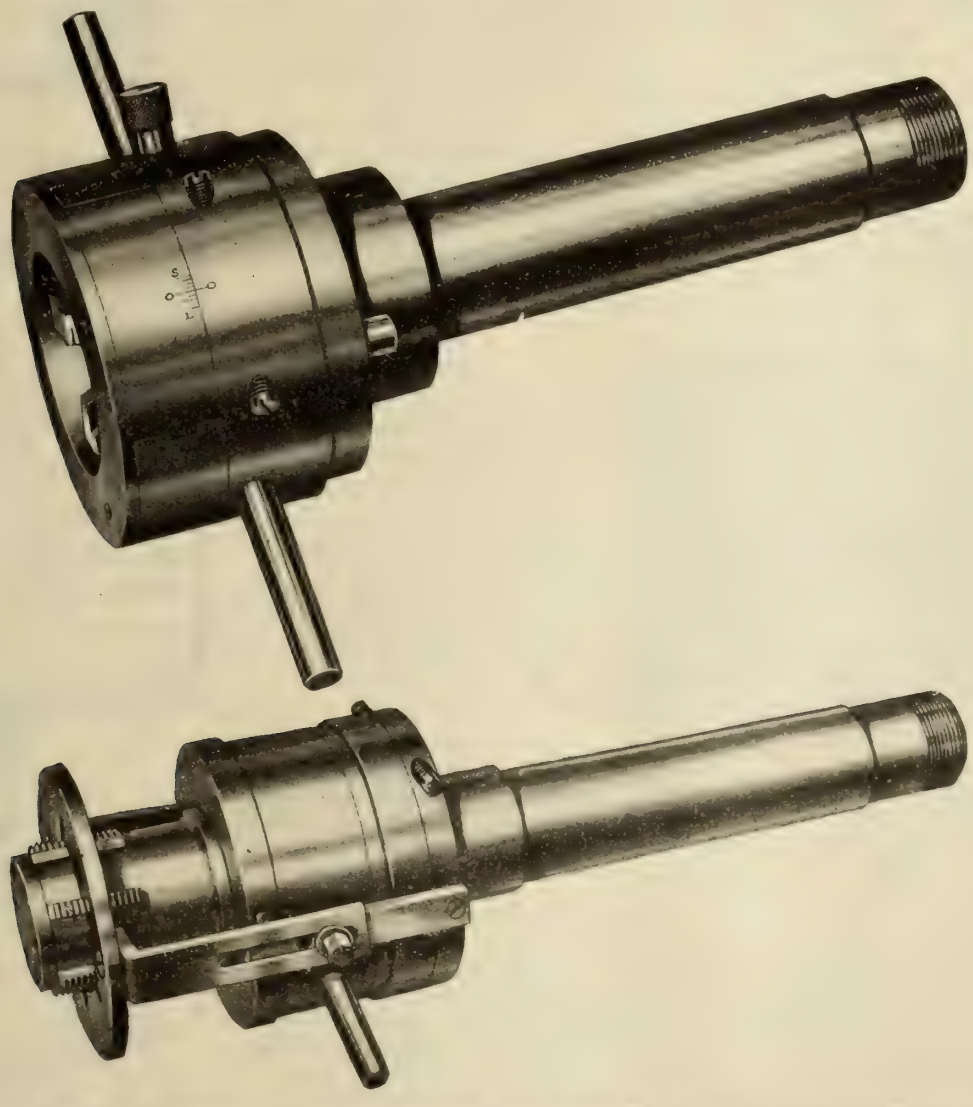
Procedure Which Should Be Adopted. Fees and Other Particulars.

Canadian firms who are now exporting, or intend to export to the West Indies, and who are proprietors of trade marks, are strongly recommended to have them registered in each of the colonies. According to Trade Commissioner E. H. S. Flood, the procedure is very simple, and the fees charged are not excessive. He says that applications for the registration of a large number of foreign trade marks have been advertised in the Official Gazettes of the various islands during the last few years, but not many Canadian have appeared. In some countries a trade mark once registered, though it may be fraudulent, can be held against the owner, but in the British West Indies the courts afford relief, and fraudlent trade marks may be cancelled. The method of procedure to obtain registration of trade marks in Barbados, is as follows:—

The registrar states that the laws governing trade marks and merchandise marks, and the procedure in obtaining registration for them, are the same in both cases. A form of application is required, which can be obtained from the registrar, and is to be accompanied by a representation of the trade mark either on a printed label, an impression from a steel engraving, or an engraved block. On receipt of these an acknowledgment, enclosing with it a memorandum of the registration fees and cost of advertising, is made by the registrar on payment of which a notice of the application is inserted in the Official Gazette and one other newspaper for one month. A certificate of registration is then issued which does not require renewal. The fees are: application, 1 s. registration, 5 s.; certificate, 5 s.—with an additional charge for preparing a block for the printer, and about $5 for the advertising. Should a certificate of registration be obtained that is fraudulent, it may be set aside by an action in the Court of Common Pleas. Applications from foreign firms for information concening trade marks may be addressed to the Colonial Secretary or the registrar. It is quite possible that the above fees may be increased by the legislature now in session.

Information on Trinidad; The Windward Islands; St. Vincent and St. Lucia can be obtained by writing Mr. Flood at Barbados.

An Exhibition under the auspices of the Hungarian iron and machinery industries is to be held in Budapest from Aug. 15th to Sept. 30th.



GEOMETRICS

For Cutting Screw Threads

GEO MET RIC

Right on the Lead

Self-Opening and Adjustable Die Heads and Collapsing Taps made in many styles for the many makes of Machines employed in producing Screw Threads.

Geometric Die Heads and Collapsing Taps are furnished with specially threaded shanks to fit them for use in the special threading fixture provided on the Gridley Single Spindle Automatics. Whatever make of machine, there is a Geometric to fit it.

Canadian Machinery

TRADE GOSSIP

The National Slag Products Ltd., are busy erecting a modern plant at Hamilton, Ont. The raw material needed for construction is being provided on contract by the Steel Co., of Canada. This new company will manufacture building tile, bricks, roofing, slabs, floor slabs, field gram tile, fence posts, door and window lintels, door and window backs, and allied lines and will utilize a special process in their manufacture. A market for these products has already been arranged and the plant will have an initial minimum capacity of 6,000 5" x 8" 12" tiles per day.

The company is capitalized at $300,000, of which one-third is 7 per cent. cumulative preferred stock, and the remainder common stock. Of the latter only one-half, or $100,000 is being issued at present. No public offering of stock will be made, as most of it has already been taken up by private subscription.

The board of directors, who are well-known engineers, contractors or financial men, include: William H. Yates, president; David Rick, vice-president; J. P. Anglin, Hon. G. D. Robertson, H. J. Daly, W. R. Fleming, Gordon Hutton, and E. J. Robertson, manager and secretary-treasurer.

* * *

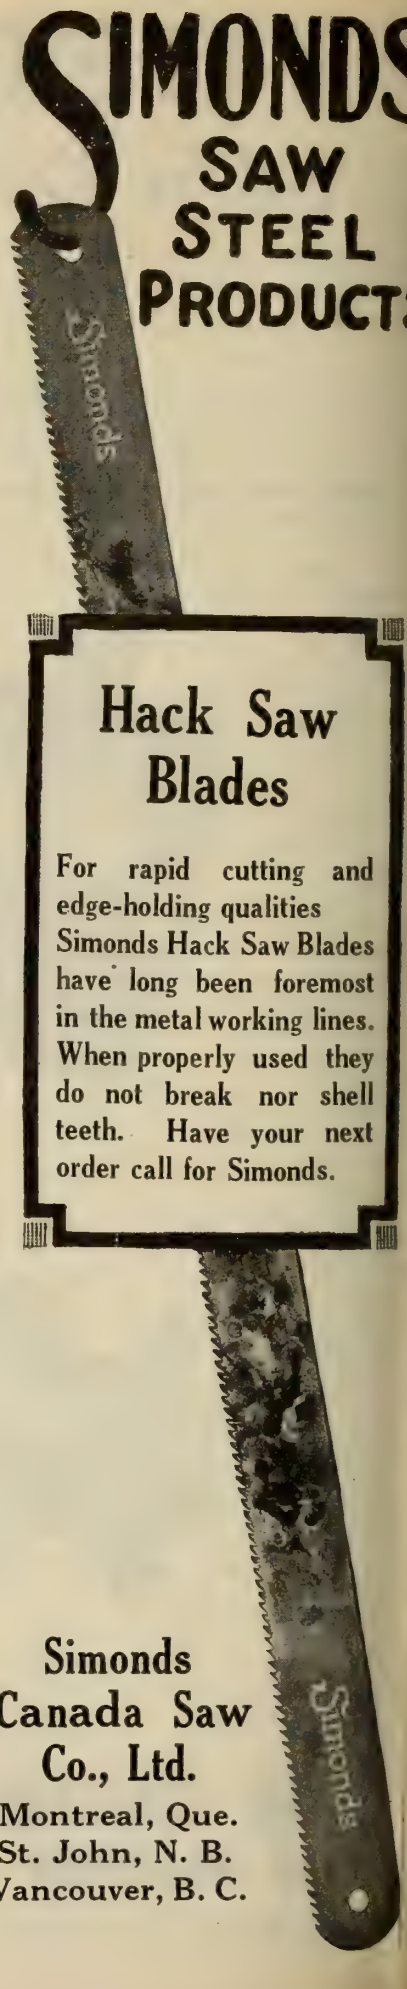
Heavy decreases have taken place in the import of lumber of all kinds from Canada, reports London England, and the same holds good regarding paper, although wood pulp receipts were greater.

* * *

According to reports the Australian state governments are giving financial assistance to firms experimenting in the manufacture of paper from Australian woods. So far, the results have been very encouraging.

* * *

The fair which will be held in Lyons, France, from Oct. 1st. to 15th, should be of great importance in the promotion of international trade. Every effort is being made by the promoters to secure representatives from every country.



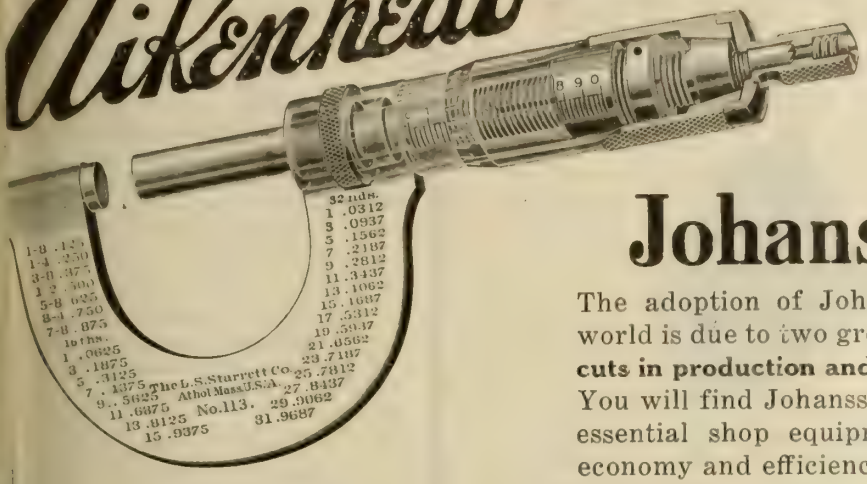
* * *

According to reports, Belgian steel, profiting by the exchange situation, has succeeded in undercutting the production of Australian mills, thus defeating the tariff as a protective measure. It is stated that Australia has been canvassed at prices much below market rates.

* * *

The eight hour day has become law in Belgium, the King having given his official assent to the movement. It has been pointed out however that the law will not suppress foreign competition, nor the necessity for cheap production. One good feature however is the fact that the workmen have taken to the piece work idea and a good output has been secured in many lines of industry.

SIMONDS SAW STEEL PRODUCTS



Hack Saw Blades

Aikenhead's

Johansson ACCURACY

Johansson Gauges

The adoption of Johansson Gauges all over the world is due to two great factors—**they make short cuts in production and cut manufacturing costs.** You will find Johansson Gauges are considered as essential shop equipment in those shops where economy and efficiency is carefully studied.

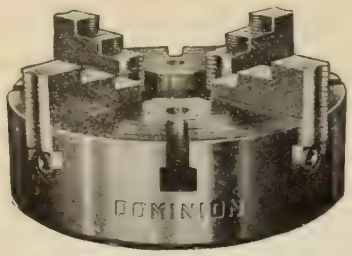
The Johansson book tells all about them. Write for yours to-day.

Johansson Adjustable Limit Snap Gauges eliminate the cost of making and maintaining solid snaps. They eliminate the tendency of the operator to work to "absolute dimension" and get results even in the hands of unskilled operators.

Single Spindle Hand Tachometers

Hand Tachometers supply the need for accurate, durable and handy speed recorders for all-round use. They indicate accurately the revolutions per minute, either right or left hand, of shafts and spindles; furthermore by using the measuring disc, periphery or surface speeds are determined. The result (either revolutions per minute or feet per minute) is instantly shown on the dial without watch-timing or calculating of any sort. The slightest variation in speed occurring during a fraction of a minute is also shown at a glance. Belt slipping and consequent loss of power is, therefore, quickly detected.

Aikenhead's



"Everything in Tools"

The reputation of a manufacturer's product is his greatest asset. The firm which represents him to the purchaser must have a reputation equal to his own.

TRADE GOSSIP

Owing to the depression in Japan the trade commissioner for Canada in that county has found it practically impossible to interest dealers in Canadian lines. Importers do not wish to enter new business until present supplies have been almost exhausted.

* * *

Shipbuilding in the United Kingdom is much depressed at present. There is a hope however that the bottom has been reached. As compared with figures for the March quarter, the latest report shows a reduction of 104,000 tons in the tonnage launched.

* * *

The Morse Chain Co., Ithaca are going to have an exhibit at the Exposition of Chemical Industries to be held in Chicago during the week of Sept. 12 1921.

* * *

A commission has been appointed to calculate building and working expenses for exploiting the orefields near Kiruna in Lapland. The ore has been examined and the percentage of iron is between 65.5 and 68.5, and of phosphorus .00 to .008. The quantity of ore is estimated at 35 to 40 million tons.

FIRMS WANT TO SELL OUR GOODS

Information regarding the following lines can be obtained by communicating with this paper and mentioning the numbers.

3250. **Products for France.**—A firm subject at present attached to the French Commission in New York and shortly returning to France, desires to represent Canadian manufacturers and producers for that country and Europe in general. Following are some of the goods he is prepared to handle: textos, minerals, manufactured products such as agricultural machinery and paper pulp.

3236. **Trade with India.**—The London office of an Indian house is anxious to be put in touch with Canadian exporters of lines suitable for the Indian market.

3237. **Hardware and Metals.**—The London office of an Indian house is anxious to be put in touch with Canadian exporters of all kinds of hardware, tools, iron and steel staples, building materials, enamelware and kitchen utensils.

A FLOATING EXHIBITION

An original method of advertising British manufactures is being developed by an influential company. A big liner of a special type will be constructed with accommodation for a large number of exhibits and with room also for many exhibitors and crowds of visitors. The ship will call at numerous ports throughout the world and will therefore, form a floating exhibition of British productions.

Chicago-Detroit Harrison, N. J. England-France

WE MANUFACTURE RIVETS of every description, 5/8 inch dia. and smaller

PARMENTER & BULLOCH CO., LTD.
GANANOQUE, ONT.

DAVIS-BOURNONVILLE

Hand and machine torches for cutting wrought iron, steel and cast iron.

Torches for shipyards, boiler shops, bridge works, and forge plants. Costs of fabrication greatly reduced by the intelligent use of modern torch equipment. Special cutting tips for cutting off rivet heads and staybolts.

Style 82 tip for cutting cast iron fits all D-B style C heads.

WELDING AND CUTTING DAVIS APPARATUS DAVIS-BOURNONVILLE CO.

Davis-Bournonville Company
Jersey City, N.J.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

THE K–T FOUNDRY GALT, ONT.

TRADE K–T MARK

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in mold cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

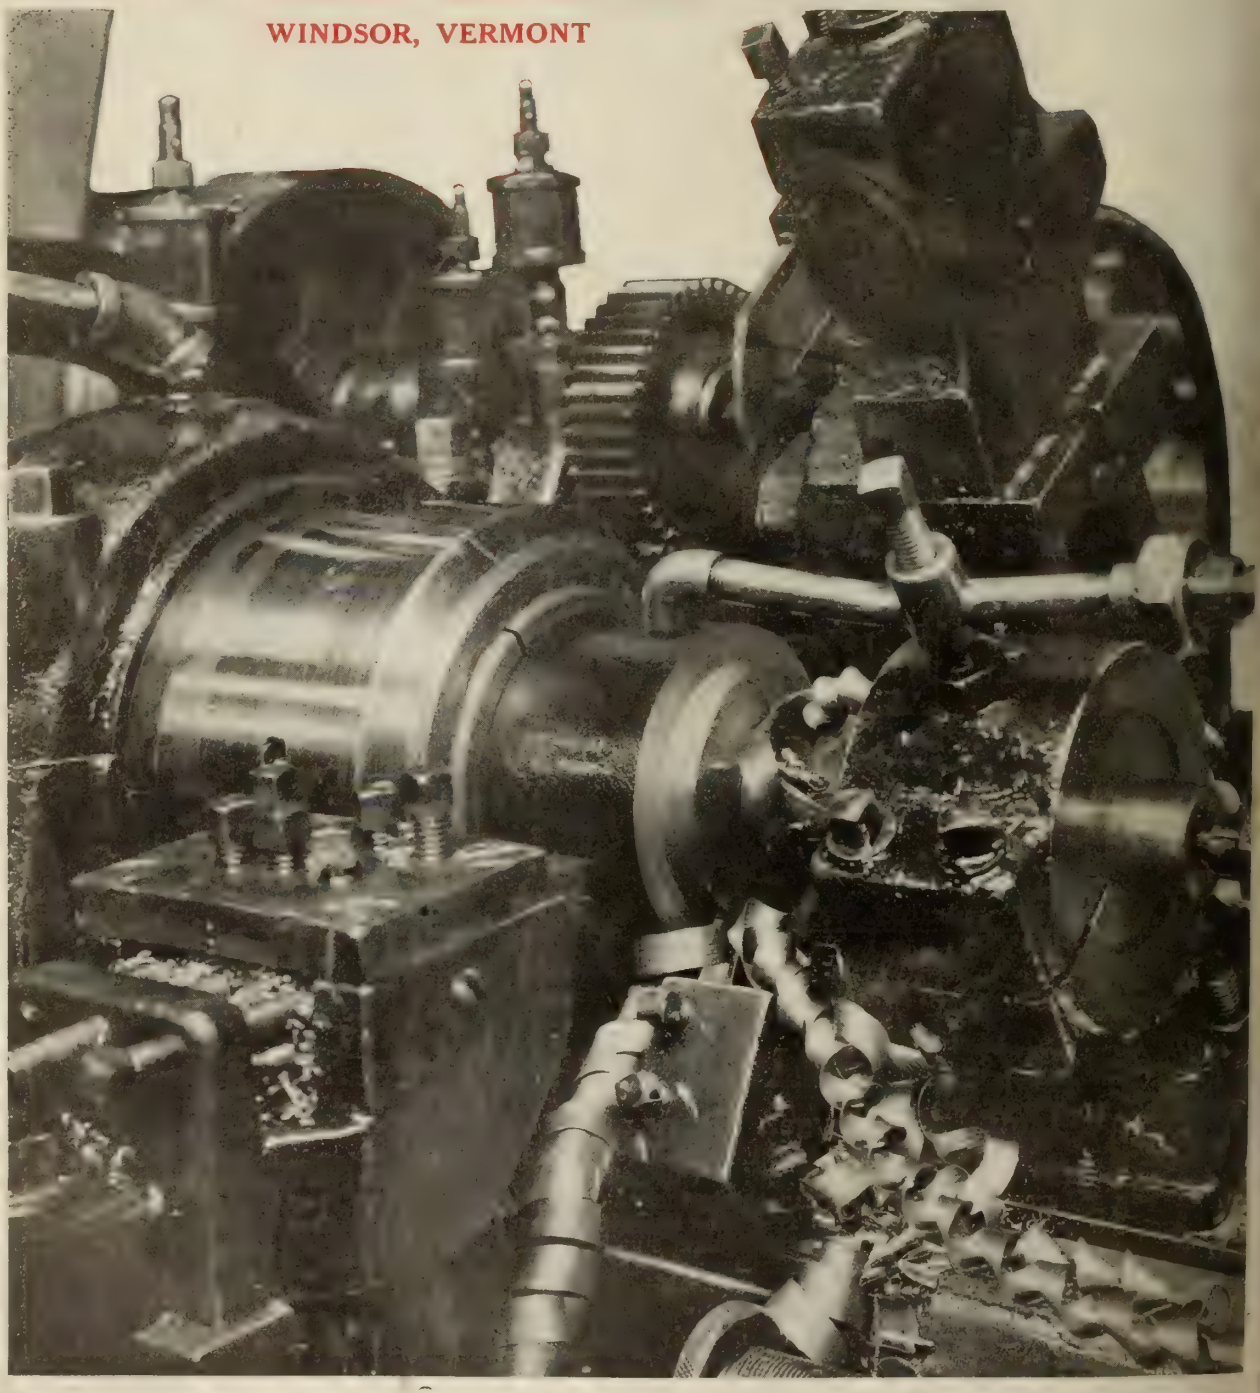
OPERATED IN CONJUNCTION WITH A CONTINENT WIDE NET-WORK OF DISTRIBUTION STATIONS

"Liquid Air" Oxygen Means a Saving in Transportation

With a network of Factories, not only planned but in actual operation, and a number of Distribution Stations situated at all large centres all over Canada. Purchasers of Oxygen can obtain their supplies at a point very near to the point of consumption. This completely obviates heavy freight charges on cylinders and assures an immediate supply at any time within a few hours and even minutes after the orders are placed.

All cylinders conform to the specifications of the Canadian Railroad Board and are made to ensure safety without unnecessary weight. When purchasing "Liquid Air" Oxygen you not only save on freight but in very many cases this expense is almost eliminated.



All day long—six days a week

You know it takes a sturdy well-balanced machine to turn a job like this on a heavy feed and get a smooth even chip.

You can get results like this all day long, six days a week, on a Gridley Single Spindle Fully-Automatic Turret Lathe. Find out how many.

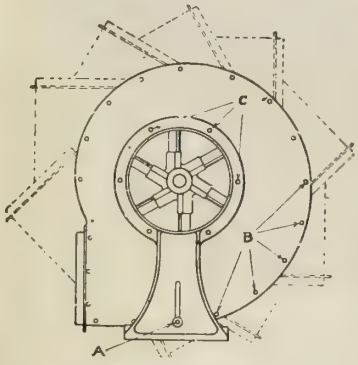
THE TORONTO IRON WORKS LIMITED
HEAD OFFICE: ROYAL BANK BLDG. TORONTO WORKS: CHERRY STREET

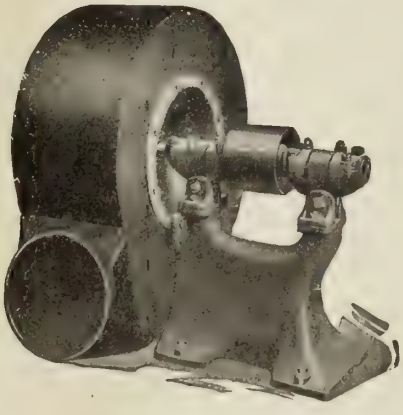
Canadian



The Canadian Standard Reversible Mill Exhauster will keep your shop clean, remove sawdust, shavings, fumes, gas or any loose materials and disagreeable odors.

Insurance rates can be reduced; floors and machines covered with sawdust, chips or shavings, increase the fire risk.

Insurance companies reduce the premiums where adequate precautions have been taken to prevent fires.

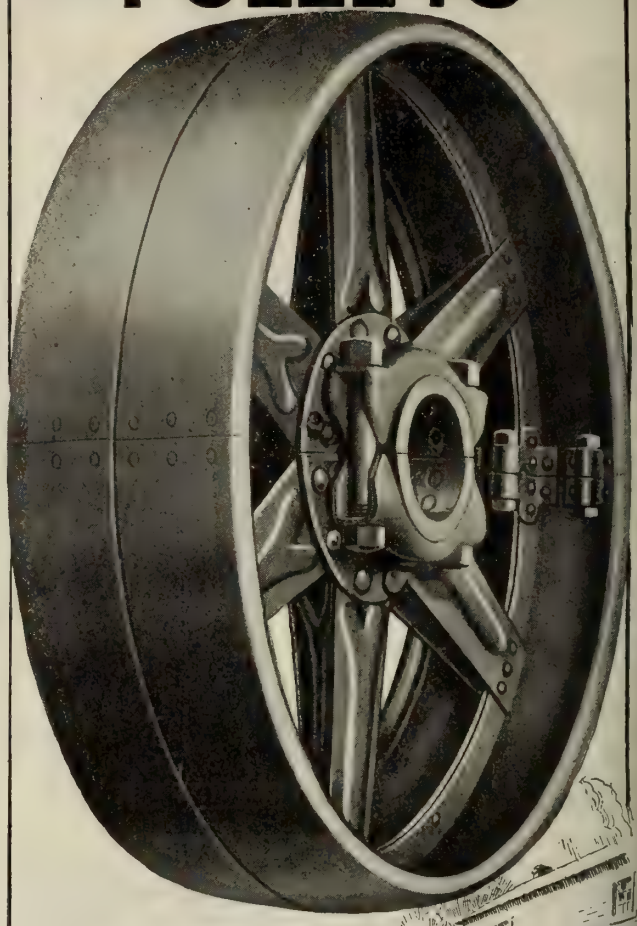


Blast Wheel — This wheel is so constructed that it will handle any kind of stringy material efficiently, such as sawdust, shavings, cotton lint. Will also handle gases, fumes, smoke, etc.

The Canadian Standard Planing Mill Exhausters have reversible housings so that the outlet can be adjusted instantly to any angle desired.

This eliminates necessity of crossed belts. Simplifies changes on alterations in piping or building.

The housing is of heavy rolled steel plate securely bolted together with angle irons. round cast iron outlet bolted to the housing. Blast wheel mounted on heavy cast iron spider.



Every fan carefully tested by running test at speeds in excess of that required.

AMERICAN STEEL SPLIT PULLEYS

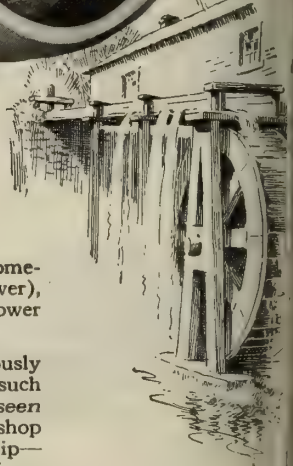

Figure the Cost of Pulleys in Terms of Saved Power

THE old sluiceway sometimes leaked water-(power), but who cared? That power was cheap—yet

Today, with tremendously expensive power costs, just such wastes are occurring *unseen* in the average machine shop through excessive belt slip—excessive friction in bearings, dead weight of pulleys that consume power.

How to overcome these troubles is explained in our book, "Getting Maximum Pulley Efficiency."

The American Pulley Company
Philadelphia, Pa.

The AMERICAN PULLEY
A wheel with a broad rim transmitting power from or imparting power to machinery, or changing the direction of motion by means of a flat belt.

WE ARE EXHIBITING THE FOLLOWING

Machine Tools on our Stands in the Machinery Hall

AT THE CANADIAN NATIONAL EXHIBITION, TORONTO

AUGUST 27th to SEPTEMBER 10th

Herbert Hexagon Turret Lathes for Bar Work.
Herbert Combination Turret Lathes.
Herbert Ball-Bearing Drills with Self-Engaging and Self-Releasing Feed.
Herbert Milling Machines.
Kearns Horizontal Boring, Facing, Milling and Drilling Machine.
Lumsden Oscillating Tool Grinder.
Pollard Drilling Machines.

Most of the Machines Will be Shown in Operation

e confidently believe all users of machine tools will find a visit to our stands of considerable interest.

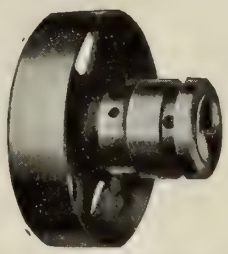
THE JOHNSON FRICTION CLUTCH



It's a Johnson Lineshaft Drive

A battery of twelve light presses, all on a bench about 30 x 5, driven from one lineshaft with Johnson Clutches controlling the machines.

Illustration by courtesy of The New Departure Manufacturing Co., showing bench presses in operation at their Elmwood Plant.

FRICTION CONTROL MEANS BETTER MACHINERY

We specialize in applying the proper type of friction clutch on any sort of an installation. Standard clutches available from stock, and special models developed to suit conditions.

COMPARE IT FOR FIRST COST

Twelve Clutches against twelve complete counter shafts, or twelve individual motors.

COMPARE IT FOR EFFICIENCY.

Quick, smooth control against the sluggish tight and loose pulley. Or one motor consuming current instead of twelve.

COMPARE IT FOR SERVICE.

You know the failing of belts—the continual attention they require, especially when they are shifted. If you don't know Johnson Clutch Service, just give it a trial.

Write for our booklet

"Clutches As Applied to Machine Building." and our Yellow Catalog.

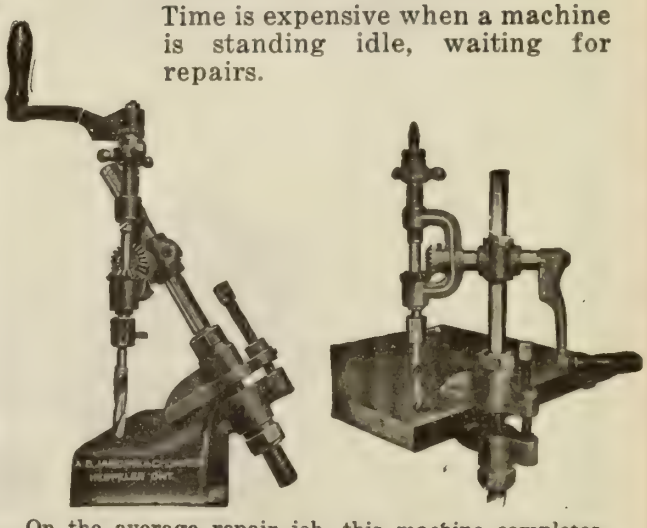
LA SALLE

Has an Advantage Over Other Grinders

There is some outstanding feature of all La Salle Grinding Machines that lends it exceptional productive ability.

The American Drill Grinder is especially adaptable for grinding twist, flat and three-lipped drills, because it has automatic lip rest and caliper jaw device, which assures proper clearance on all sizes of drills automatically. Send for descriptive matter covering our entire line of grinding machinery.



American Drill Grinder
For Wet or Dry Drill Grinding 1/8" to 2¼". Also 1/8" to 3½" dia.

The illustration below shows the three protective coatings which provide an impregnable shield for the specially annealed steel which forms the core. An actual sample will be sent to you upon request.

Stopping Maintenance Leaks

Maintenance costs offset profits. Frequent painting, endless repairs and replacements are eating up funds that might otherwise go into the profits of many manufacturers.

During the present business period it is all the more necessary that needless depreciation and repair costs be eliminated. They can be eliminated by a choice of your building repair materials.

Robertson Process Metal is a building material that ends needless expenditures. On your buildings *it stops painting.* It is rust proof, weather proof, and corrosion proof and therefore reduces repair expense. It is protected against deterioration. It will go a long way toward *stopping your maintenance leaks and heavy depreciation losses.*

The process illustration shown here will tell the story of Robertson protection. You can see how one impervious coat after another is pressed upon the steel (1) Asphalt (2) Asbestos (3) Waterproofing, building up a thick layer of non-corrosive, moisture-proof material that completely encases the metal. Neither air nor moisture can reach the steel within.

Robertson Process Metal is made in corrugated sheets for roofing and siding; also in various forms for use in factory-building trim, gutters, downspouts, etc. Complete descriptions and engineering data will be gladly furnished in bulletin form. Send for a sample today.

The pride and care which go into the construction of Brown & Sharpe Products are reflected in the long and satisfactory service they return to the user

Allen-Bradley Clapper-Type Mill and Crane Control

Two-speed Electric Slackline Cableway Hoist, used in gravel pit work, equipped with 150 h. p. Type F-2404 Controller for Alternating Current Slip-ring Motor.

The simplicity of the switch gear used with a compression resistor has led to the development of Allen-Bradley Clapper-Type Mill and Crane Control, incorporating a mechanically operated, heavy duty switch gear of the Clapper-Type, in combination with the well-known Allen-Bradley graphite compression resistor.

In this controller the graphite compression resistors supplant grid or wire resistors, and being mounted within the controller, dispense with the complex wiring between controller and grids. Individual resistors are removable without disturbing existing wiring or other resistors. Controllers can be supplied for mono-rail trolleys, small hoist control, average and heavy duty mill and crane service.

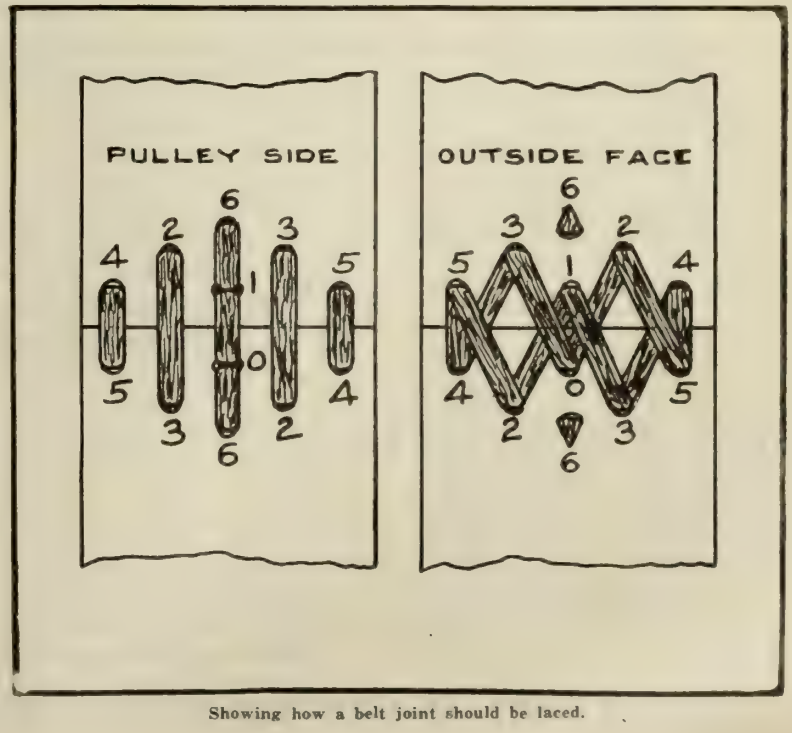
The Proper Care of Belting—Points to Watch

Selection of Belting—Importance of Proper Alignment of Pulleys —Various Types of Belt Joints—Method of Preparation—How to Keep a Belt Effective—A Record Should be Kept.

By J. H. MOORE.

IN COMMENCING the subject of "The Proper Care of Belting" let it be thoroughly understood that we are going to discuss the many phases of transmission trouble which can ruin the best belt in the world. An improperly aligned, or a poorly supported belt will, in a short time, cause endless trouble with the belts. These are only two of a great many troubles, so that transmission difficulties can well be left out of the present article, to be discussed separately at a later date. There are few users of belts who give the attention they deserve, and undoubtedly a fallacy exists that a tight belt is all that is necessary. A tight belt in many cases is very desirable, but there is more to it than this. Some mechanics will tell you that if a belt gets slack, take off, chop a piece out of it; replace it and stick her on again. We use the manager of the shop advisedly to show with what contempt a belt is often held.

Before a belt is installed, all possible stretch should be taken out of it. This can be accomplished by means of any of the stretching devices at present on the market. If at all possible the task of keeping the belt in proper shape should be handed over to one man. Incidentally speaking, the belt supervisor should be a good man, not merely a handy laborer. Employ a man who understands belts; who realizes that temperature and climatic conditions have to be reckoned with; and who has the powers of imagination. The latter characteristic helps him to picture what he would feel were he the belt.



Just think for a moment what a belt has to undergo on a jerky drive. Picture the belt winging round the pulley of the driving machine. The strain rises suddenly from practically nothing to a pull of several hundred pounds as the belt leaves the driving pulley on its trip to the shaft. Add to this normal condition a jerky drive (and they are often found),—what ensues? While the belt is tightly stretched under the pull it is violently jerked and tugged, really placing the big strain on it at the worst possible time. If the machine is not running smoothly the belt is alternately let down and tightened up on the slack side, and each tightening creates a sharp, sudden strain that eventually tears the belt to pieces. Have you ever seen a belt that was fairly slack act just like a whip? Of course you have; but did you ever stop to think how you would stand up to such sudden tightening and slackening? And now, since we have pleaded the cause of the poor neglected belt, we will consider how to overcome some belt troubles.

Selection of Belting

When selecting belting many things have to be taken into consideration. Assuming first of all that a leather belt is going to be used, uniformity in the material is of very great importance. It pays to purchase a high grade belt, for while the initial cost may be greater, the service received will more than make up for the extra cost. As previously stated the belts should be thoroughly stretched before using so that they do not have to be "taken up" every few days.

Where belts are exposed to the weather or to the action of steam, rubber belts are generally used as they do not absorb moisture or stretch as readily as leather under like conditions. Again comes the question of quality. The best grades of such belting contain nothing but new rubber, while others are made largely of reclaimed rubber. High grade belts contain a heavy make of cotton duck, while the cheaper grades have a lighter quality of duck. Providing the proper grade of duck is used a 3 or 4 ply belt of this nature is said to be equal in strength to a single leather belt. A 5 or 6 ply belt is about equal to a double leather belt and so on in proportion.

Canvas stitched belting again is often used when the material coming in contact with the belt, or the surrounding atmosphere would ruin an ordinary leather, cotton, or rubber belt. Such belts are al-

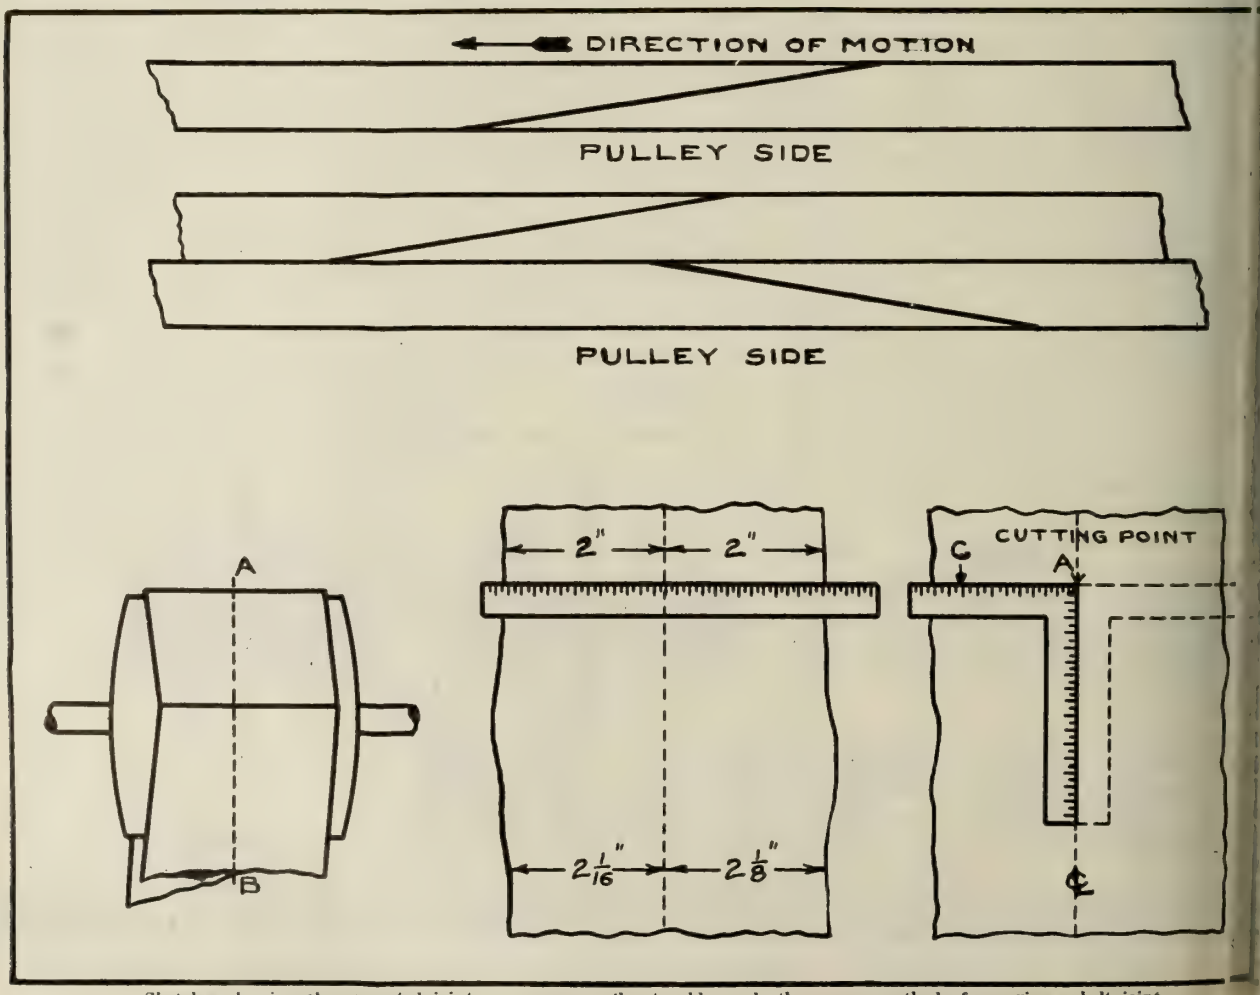
Showing how a belt joint should be laced.

so applicable to belt conveyors, when the material to be handled will not cut the cotton fibre. Steel belts are also used, especially in England and other European Countries, and for information on this latter subject we would refer readers to the June 21st issue of Canadian Machinery. Of course there are all makes and grades of belting, each manufacturer claiming for his particular product some inherent advantages. A good plan is to use sufficient for a test drive, place it under the worst conditions possible, then watch results. Once you get a belt to suit you, stick to it. True you can still continue an occasional test drive, but until you have definite proof of the new belt's qualities, keep using what you have found to suit your purpose.

Belt Joints

An endless belt can naturally run smoothest when there is no obstruction to cause it to jump. For this reason some claim the cemented belt joint to be the most satisfactory. The accompanying sketch shows clearly how such joints are made, and in making the joint the belt ends should be tapered to a smooth, even surface, keeping them, of course, square with the edges. Depending upon the width of the belt, the length of the lap can vary, and the following figures have been found to give excellent results:— For 1 in. width belt, length of lap. 5 in.; 2 in. belt, 5 in; 3 in. belt, 6 in; 4 in belt, 6 in; 5 in. belt, 7 in; 6 in. belt, 8 in; 7 in. belt 8 in; and 8in belt, 9 in. of lap. Above this width the length of lap is usually made equal to the belt width, and after 18 in. wide belts have been reached, the lap need go no longer than this amount.

Before cementing a joint of this nature the belt should be placed over the pulleys and the proper tension obtained by means of clamps. After drawing the belt a little tighter than is necessary, to allow for slack, level the ends to form the lap, applying the cement to both surfaces while hot. Should the belt be very large, cement only a few inches at a time, then hammer down the cemented section thoroughly, proceeding in this manner until the complete joint has been cemented. Last, but not least, the joint should be hammered carefully along the edges. The clamps should be left on for at least an hour, longer if possible. In the case of smaller belts, the cemented lap is often clamped between boards to which the belt has been previously tacked in proper position. There are various cements used, some home made, others which can be purchased, but it is the method rather than the cement used which interests us.



Referring to the sketch, it will be noted that the point of the lap is on the pulley side. The lap is placed in this way to prevent the end from opening, for when the point is to the outside the tendency is to open up, especially if the belt is travelling at a high rate of speed. On a double ply belt the laps should be arranged as shown in the other sketch. With this arrangement the points of the laps in both piles will be to the inside, this way being protected. Of course o[ther] on this method differ but the pra[ctice] shown has been found to give ex[cel]lent results.

The Laced Belt Joint

There are several ways of lacin[g] but the sketch shows a very satis[factory] method of lacing. When making joint, cut the ends of the belt 'p[er]' square. Do not make the holes any than absolutely necessary, for ot[her] you will only weaken the belt at [the] ched section. In making a joint i[t is] visable to use a good strong thin [lace] preference to a thick one. The [more] the lace the less will be the jar on e[ach] as it goes round the pulley. The [best] lacing should always be kept on [the] ley side, and as a general rule th[e num]ber of holes for belts of various [widths] can be as follows:—

For 1 in. to 2 in. belts, ¼ in. v[ide] ing is sufficient, and three holes [each] side of the joint will do. From [1] 4½ in. belt, 3 to 5 holes at each [end] all right, and from there to 5 in [belt] wil be found sufficient. From [6] 9 to 17 holes are usually punc[hed] pending upon conditions and th[e] of the drive. The lacing usually [used] ranges from ¼ in. in the smalle[r] ½ in. in the larger belting, b[ut] 6 in width ⅜ in. lacing will b[e] enough.

The distance that the holes s[hould]

Sketches showing the cemented joint—a common pulley trouble, and the proper method of squaring a belt joint.

nch from the end remains an open
est, but good practice calls for the
st w in the smaller belts ranging
m in. to ½ in. from the end, the
one row being back from ¾ in. to
n. bove 4 in. width, the holes go
k proportionate distance.
The est practice is to commence at
ce er and work out and back on
b ple. The figures on the illustra-
n a Fig. 2 can be followed out in
w. Starting at 0 and 1, the order
is llows:—2, 3, 4, 5, 4, 3, 2, 1, or
ot sides of the center being identi-

ef ower transmission. A belt
co taining resin or mineral oils
ma be used, as these ingredients
are trimental. Never use a belt
co taining animal oils on rubber,
or titched cotton duck belting.
Th er time to apply belt dress-
is wh n the plant is closed down for
ov ; for instance, Saturday, as
Mo da morning it has had a chance
ab the belt and keep it soft and
pliable. If kept in this condition there is no excuse for anyone resorting to the questionable remedy of applying resin, or any sticky dressing to get the proper power out of belts.

Belts used in saw mills and other plants that are shut down during the winter months should be taken off, rolled up, and kept in a warm place. If left on the pulleys and exposed to the changeable atmospheric conditions of a Canadian winter they will certainly have deteriorated by spring. Carelessness in starting up machinery too quickly is liable to cause belts to slip on pulleys, thus injuring them. This can be obviated by putting on the power gradually, which gives belts a chance to get a grip on the pulleys.

Another important matter is to have proper alignment of pulleys, as many belts give out before their time owing to defects in this respect. Another mistake made by some belting users is practising false economy in getting belts too light for the work they have to do. While a certain weight of belt may at first do the work required, if it is necessary to keep it on a constant strain to accomplish this, both belt and machinery are going to wear out much faster than if there is a "reserve." In other words, heavy enough belts should be used to ensure their not being overstrained. This may cost a little more at first, but pays in the long run.

The Federal Engineering Co., Ltd., Toronto, Canada speaking on the same subject ask this important question: Why do so many firms spend so much good money in buying good belts, and not give them necessary attention afterwardsi

In order that a belt may remain efficient, they continue, it must be kept pliable. No matter what kind of belt is used there are two enemies at work, each trying to shorten the life of belting. These are hardening of the belt fibre and belt slip.

Hardening of belts to our mind can be absolutely avoided by belt dressings, but all belts must not be dressed in the same manner. For example, our Scandinavia belts, which are solid-woven, and filled with a bituminous dressing, can be kept soft and pliable by dressing occasionally with the same material with which the belt is impregnated, or in place of this material castor oil may be used.

For leather belts either of the above dressings may be used, or many of the bar belt dressings on the market. Do not, however, use bar belt dressings on Scandinavia or other textile belts. The textile belt should have a liquid dressing which will soak well into the fibres of the belt. Liquid dressings should be applied warm, and with a brush to the pulley side of the belts. Once a month is not too often.

Rubber belts do not require any dressing. Balata belting may require a little attention of this kind at times, but great care is necessary. The only time a Balata belt requires dressing is when the pulley side of the belt becomes smooth and glossy. The dressing to be used is castor oil, and this should be put on just a drop here and there. This castor oil sparingly applied, after the belt has been run, will give a "tacky" feeling to the surface of the belt, which will stop slipping. We have seen thousands of Balata belts ruind by having too much oil or improper belt dressings used on them.

Recently we had two of our Balata belts returned to us to have the ends respliced, as the splices had come apart. On examination the belt was found to be soaked with oil. This oil had dissolved the balata gum, allowing the splices to slip apart, and permitting the plies to open up. We made up the splices again, cautioning our friends against using oil or dressing on this kind of belting. They wrote back that they had been using bar belt dressing. This kind had been recommended to them for use on their leather belts, and they were using it on all belts. Never use belt dressing of any kind on such belts, and only a very little castor oil, as previously directed. It is better to let these belts go without dressing than to put too much oil on them.

With regard to slipping of belts, this is a very serious evil. Often it is only detected by careful observation, and by tests. The result of belt slip is cracking across the width, and when you find a belt cracked in this way you can rest assured that your belt has been slipping. This defect must be remedied as soon as posible, or it may cost a lot of money in ruined belting.

First, examine the belt and see if it is soft and pliable. If it is not, the belt should be made so immediately.

If it is soft, and still slipping, it may require adhesive, provided the belt is not overloaded. Belting running from large to small pulleys with comparatively short belt centres nearly always requires an adhesive, but it should not be used on all kinds of belting. For instance belting made in plies is apt to be pulled apart in the plies or splices from the drag of this material.

In conclusion we would suggest some system whereby a record can be kept of the different belts and their performances. Various plants are finding such a plan to be of advantage. For example, suppose you require a belt. Place a steel tape over the pulleys and determine the correct length required. Place this length, together with other particulars of the belt used, the nature of the drive, etc., on a card, keeping this on file. State the date of application and leave spaces to record when the belt needed repair, when it should receive its dressing, etc. Do not forget the cost. Do not be afraid to put everything of importance on the card for this is the only true method of actually knowing what your belts are costing you, and what grades are standing up best. If such a plan is inaugurated there will be less idle machines in manufacturing plants. A foreman wouldn't think of allowing a laborer to operate his high class machines; why then should he let any Tom, Dick, or Harry, attend to the belts which keep those high price machines in operation.

Operating Compressed Air System Efficiently

The Successful Operation Depends Largely Upon Provision Made for Receiver of Sufficient Capacity—What to Do if Demand Fluctuates — Various Examples of Installations

By JOHN S. WATTS

THE successful operation of a compressed air system depends more largely upon the provision of a receiver of a sufficient capacity, regarded as a reservoir, than is commonly understood. It is a common custom to refer to the catalogues of manufacturers of air compressors, who give the sizes of air receivers that are usually used with a given size of compressor, and while the size of receiver they recommend is sufficient for average conditions, with a fairly steady demand for air, the capacity should always be looked into by the engineer who is responsible for its installation, and checked up by as close an estimation of the requirements as the case will permit.

Where a fluctuating demand is to be supplied, it is much more economical to instal a large receiver than it is to have a large compressor, the difference in first cost being considerable. Further, in operation, it is much easier on the machine, to have it running under a steady load, as it will with a large enough receiver, than to have the compressor large enough to carry the peak load and be constantly dropping the load and picking it up again.

The capacity of an air receiver, as a reservoir, is the quantity of air which it will give out between the pressure at which the unloading valve on the compressor cuts off the supply and that pressure at which the tools being driven by the compressed air will fail to function properly because of too low pressure.

For example, we will suppose that the unloading valve closes at 100 pounds gauge pressure, and that the lowest useful pressure at the air receiver is 80 pounds. This is a range in absolute pressures of 115 to 95 pounds, or 20 pounds expansion. In thus expanding from 115 to 95 pounds, the ratio of expansion is 20/115 or 0.174; that is, at constant temperature the receiver will deliver 0.174 of its cubic contents in falling from the highest to the lowest allowable pressures.

Taking the average sizes of receivers recommended for use by the makers of air compressors, we find that the total cubic contents of the receivers vary from about one-fifth of the capacity of the compressor (in cubic feet of free air per minute) for small compressors to one-fifteenth in large ones. The compressor capacity is given in terms of cubic feet of free air, that is at atmospheric pressure, which must be converted into its equivalent in cubic feet of compressed air at the temperature of the receiver which, if we take this temperature to be about that of the atmosphere, will make the delivery into the receiver about one-eighth of the compressor capacity in free air.

The reservoir capacity of the standard receivers as usually installed is about 1.6 for small compressors, to one-half for large ones, of the rated capacity of the compressors in terms of compressed air per minute. That is the receiver will take care of an overload of 100 per cent. for 1.6 to ½ minute respectively, or a 20 per cent. overload for five times these figures, viz., eight to two and one-half minutes.

It should be noted at this stage that the receivers as recommended by the makers are not intended by them to be used as reservoirs to take care of large fluctuations, but are primarily intended only to equalize the pressure in the system, which would pulsate disastrously if there was no receiver, because of the intermittent delivery at each stroke of the compressor.

The reservoir capacities as given above, in use are increased somewhat, as the delivery of the compressor in cubic feet of compressed air will increase as the pressure in the receiver falls, and in some cases this makes a decided difference in the capacity of receiver that will be required. No attempt is made to consider the variation in actual deliveries of the compressor caused by variations in the temperature of the incoming and compressed air, all of which vary the figures given, but cannot very well be allowed for, except on the assumption that they will be equal.

It will be noted that the re... capacity for large compressors i... one-third that of the small ones, t... son being that under ordinary ... tions the larger compressor will ... plying air to a large number of ... which will tend to a steadier ... than if only two or three machi... being driven, when it might occ... all of them would start and stop ... same time.

John Conley Receives Advice on Thread Cutting

The Difference Between Lead and Pitch—The Use of Indicators —Examples Worked Out for Instruction Purposes—Method of Gearing Up Lathe—How to Cut Taper Threads.

By J. DAVIS

"HOW are you getting along with your thread cutting?" John Conley looked up at his father plied:

"N very well. There are a lot of g I don't understand, and on some the men in the shop do not agree."

"t's quite likely, son. I can re- some things I believed for years, e day woke up to the fact that I wrong, but tell me some of the hat are troubling you."

"right, dad. First, what is the ce betwen the lead and the

"pitch of the thread is the dis- e etween the center of one thread center of the next. The lead is ance the screw moves endways evolution."

"e lead and the pitch are one and e thing."

"always. That is the case in a lehread screw, but not in a double iple thread; so that in making culations for thread cutting al- nsider the lead, and not the

"the pitch not cut any figure at aring up the lathe?"

"not in gearing up the lathe, but n the width of the tool."

"'s that?'

"W. if you are going to cut two in the same space as you cut one e your tool will only be half as

"athe I am running is rather old d, dad, and I have to change the r every different thread, but I of those jiggers that tell me put the nut in gear, for which y thankful."

"that indicator is quite a useful . I remember when I was run- athe we didn't have any such e used to put a chalk mark on late, another on the lead screw, until they both came to the top then put in the nut. It was work of art, I can assure you."

"ld like you to explain the prin- he indicator."

"ght, but first of all let me give al method of finding gears. The nciple of gearing up a lathe cutting is one of ratio, or pro- The ratio of the driving wheels ven wheels must be the same d of the screw to be cut is to f the lead screw. In order to s ratio the first thing to do is lead of the screw to be cut; is simple universal method. wn the lead of the thread to be form of a fraction. An easy way to express the lead of any given thread is to draw a horizontal line thus ——— placing the number of threads below the line and the number of inches above the line. The resulting fraction will be the lead of the thread."

Example: Lead of 6 threads per inch equals

$$\frac{\text{Inches}}{\text{Threads}} = \frac{1}{6} \text{ lead,}$$

and so on for all even leads. In cases where there is a fractional number, multiply both inches and threads by the least number that will bring them to a whole number.

Example: Find lead of 6¼ threads per inch. Proceeding as before: multiply by the least number that will bring them to a whole number.

$$\frac{1}{6\frac{1}{4}} = 1 \div \frac{25}{4} = \frac{4}{25}$$

Here is a more difficult one: Find the lead of 3 2-3 threads in 1¾ inches.

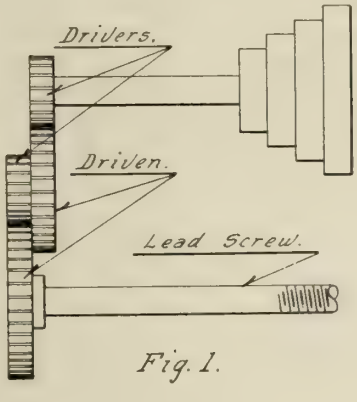
If the lead is given in decimals, bring it to a fraction by placing noughts or ciphers under each decimal figure, and 1 under the decimal point, thus: lead of decimal .75=75-100=¾, and so on.

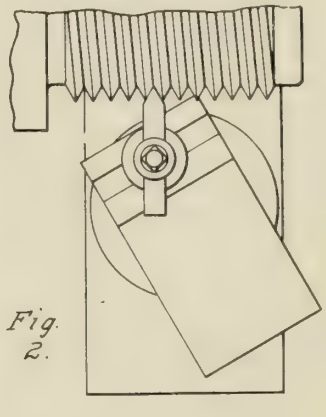
Having found pitch of screw to be cut, find pitch of leading screw in the same way. After finding lead of screws to be cut and lead of lathe screw, the next step is to find ratio by inverting, or turning upside down, the pitch of the leading screw and multiplying.

After finding ratio, a number of different sets of gears can be found by multiplying the ratio by any number we choose, but care must be taken to multiply both numerator and denominator by the same figure so as not to alter its value.

Find wheels to cut 4 threads per inch leading screw 2 threads; thread to be cut according to rule.

$$\frac{1}{4} \times \frac{2}{1} \times \frac{10}{10} = \frac{20}{40}$$





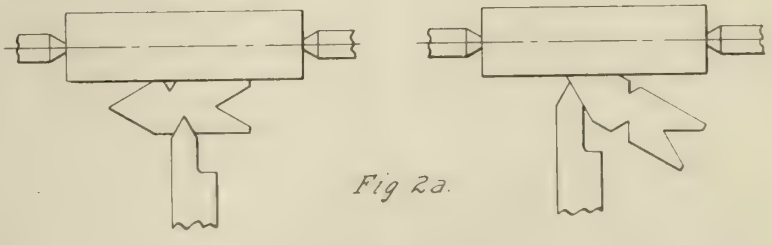


Fig. 1.

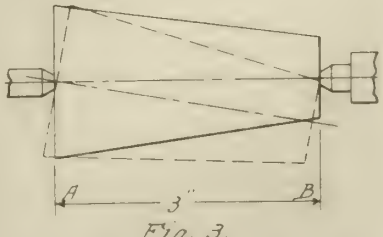
Fig. 2.

Fig 2a.



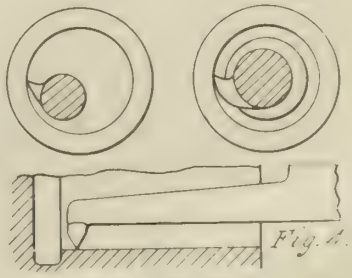


Fig. 3.

Fig. 4.

These sketches show the various suggestions in thread cutting.

Find wheels to cut 3 1-7 threads in 2 1-5 inches with a lead screw ½ inch pitch. According to rule:

$$\frac{\text{Inches}}{\text{Threads}} \quad \frac{2\ 1\text{-}5}{3\ 1\text{-}7} \times 35 = \frac{77}{110}$$

$$= \frac{77}{110} \times \frac{2}{1} = \frac{154}{110} \text{ or } \frac{77}{55}$$

from which any number of different sets of wheels may be obtained.

Sometimes it happens that the number of teeth in a gear wheel would be too large to employ a single train of wheels. In this case compound gears must be used. Here is an example that would require compound gears. To cut 24 threads per inch with a lead screw two threads per inch. Proceed to find ratio as before:

$$\frac{1}{24} \times \frac{2}{2} = \frac{2}{24} \text{ ratio.}$$

Take the numerator of the ratio, which is two, and find any two numbers which multiplied together will equal that number. Then take the denominator of the ratio, which is 24, and find any two numbers which multiplied together equal 24 or

$$\frac{2 \times 1}{12 \times 2}$$

We have now divided the ratio into four factors of equal value, which will enable us to use compound wheels. We can take any figure in the numerator or denominator and multiply, add, or subtract at will, as long as we do not alter the relative values in adding or subtracting; the amounts added or subtracted must be the same proportionate amounts of each, such as 1-3 or 1-4 or 1-5, and so on as the case may be. Take the first two figures in our example and multiply each of them by ten.

$$\frac{2}{12} \times 10 = \frac{20}{120} \text{ \& } \frac{1}{2} \times 50 = \frac{50}{100}$$

Wheels required, therefore, are 20x50 driving wheels, and 120 and 100 driven wheels.

The two top wheels are driving wheels and the two bottom wheels are driven. The sketch, Fig. 1, illustrates the position of the wheels on the lathe.

It is required to find gears to cut 16 threads per inch—lead screw ½ inch pitch? Then:

$$\frac{1}{16} \times \frac{2}{1} = \frac{2}{16} = \frac{2 \times 1}{4 \times 4} = \frac{20 \times 30}{40 \times 120}$$

To prove the wheels, multiply all driven wheels together; then multiply all the driving wheels together and divide the driven by the drivers. If the wheels are correct, you will get the same ratio or proportion as exists between the pitch of the leading screw and the pitch of the screw to be cut. Take the above example—driven wheels.

Ratio of wheels between driver and driven 8 to 1.

$$\frac{\text{Threads to be cut} \quad 16}{\text{Threads on lead screw} \quad 2}$$

Ratio required, 8 to 1.

There used to be a joke about an apprentice in the shop where I served my time who wanted to cut a thread and required a 98-tooth wheel. In those days we used to beg, borrow, or steal wheels from each other. However, he couldn't find the wheel he required, but he finished the job, and when asked how he managed it, he said triumphantly, "Oh, I wouldn't let a little thing like that stick me. I got a wheel with a hundred teeth and broke out two teeth."

"Dad, how does a prime number enter into lathe calculations?"

"I can best explain that question by giving you a concrete example. Suppose we want to cut a thread .654 lead, with a lead screw 3 threads to the inch. Find ratio according to rule. Find factors, or reduce to its lowest proportion, and we find that one of the factors is 109. Therefore it would be impossible to cut this thread without a 109 gear or a multiple of 109, because 109 is a prime number."

"I think I have got the idea of gearing up the lathe clearly. Now I want to ask you one or two questions about the actual handling or operating. What makes the tool dig into the thread and leave a nasty jagged cut, and very often break off the point?"

"In cutting a vee thread the tool rest should be moved around 30 degrees (as shown at Fig. 2), for American threads and 27½ degrees for Whitworth threads, this being half the angle of the thread. The reason for this is that when a cut is taken, the tool cuts on one side only, which gives a cleaner and better thread than is the case when the tool-rest is set at right angles to the lathe centers. In the latter case the tool must cut on both sides at once. This means a smaller cut and a rougher finish."

"How about cutting a left-hand thread?"

"In cutting a left-hand thread the direction of the rotation of the lead screw is usually reversed and the carriage run from left to right, although I have cut left-hand threads on some long sleeves by reversing the direction of the work instead of the lead screw. This had the advantage that I was able to see what the tool was doing before it advanced very far into the work."

"You didn't explain the indicator, dad. How does it tell when to engage the nut?"

"When the number of threads on the work can be divided by the number of threads on the leading screw without a remainder, the nut may be engaged at any time or place. In all other cases put down the pitch in fractional form reduced to its lowest term. The numerator will indicate the least number of complete inches that the carriage must travel after taking the nut out of gear with the leading screw before it comes to the right place to put it in again. If you have no indicator put the carriage against the tailstock for a starting place, and measure on the lathe bed the required number of inches, or some multiple of the same, according to the le th of screw to be cut. Stop the lath a this mark, and run the carriage bac to the starting place for a fresh cut. / taking the first cut, measure the th carefully to see if the lathe is cuttin right pitch. In thread cutting it i portant that the tool should be se actly at the center. If the tool is se high or too low, it will make an impe thread. When the tool commences t it is sprung to one side a little ur is advanced up the thread far enou cut on both sides; this causes a thread on the end, which is apt to d one when fitting it into place. To this, chamfer the end of the screw, finishing the thread.

In cutting multiple threads sele wheels so as to have one on the spindle that can be divided into t three equal parts as required, the ceed the same as for single thread one thread is cut, with the except the finishing cut. Chalk the bott any one space on the spindle gea also chalk the tooth of the chang which meshes with this space. If double thread, count half the nun teeth on the change gear and m the same way. Adjust the quadr swing plate so that the second tooth will mesh in the chalked sp the spindle gear, and proceed to second thread. When taking a fi cut, take the screw out of the so as to be able to move the sadd without moving the tool, drop th rant and mesh the gears at t chalk mark and finish the second The same method will do for t more threads. This is the gener cepted way for cutting double o threads, although there are othe which, under favorable circum are quicker and more convenien instance, a double or triple can b one operation by a tool that is with two or more cutting edges the lead of the thread to be cut."

"I don't want to weary you, b are just one or two more que would like to ask. In cuttin threads should the tool be set angles to the axis of the work surface?"

"Both."

"What do you mean?"

"Well, for an American th should be set to the axis, an British or Whitworth standard be set to the surface."

"We had an argument about over the tail stock for taper wo effect does this have?"

"If the center is set over by the tail-stock it will give an pitch and also a drunken threa the dead center is set over, the be in the position of the dotted sketch, Fig. 3. The work wo to be set over so that the face parallel to the center lines A pose the piece to be 3 inches that it is to be threaded 10 th

Since the length of taper, measured on the slope, is greater than the length of the piece measured parallel with its axis, it will require more than 30 revolutions to carry the tool entirely over the work, consequently there will be more than 30 threads on the piece, and it will not measure up exactly 30 threads per inch.

"Taper work should always be done with the taper attachment. When a thread is cut by setting over the tail-stock, owing to the angularity of the tail of the dog, it does not travel at a uniform speed with the lathe face plate. The end of the dog can be observed to slide back and out the notch of the face plate. Where this condition takes place, the thread cannot be a uniform pitch."

How can I overcome the spring of the tool in cutting a long thread in a small lathe?

Use the threading gauge shown at A for setting up the tool, and see that the shank of the tool is approximately parallel with the work so that the side of the tool will not rub against the thread before the point gets to the bottom of the hole. In threading long small work the biggest trouble to contend with is the spring of the tool. Many lathe tools make the cutting edge of the tool lower than the top. This means that the point of the tool must pass through a distance equal to half the diameter of the work before the cutting edge of the tool is directly over the center of the shank of the tool. As shown, a much stiffer tool can be used.

In cutting threads in very long brass bushes, the work is sometimes driven by the carriage of the lathe and the tool is carried in a parallel bar between the centers of the lathe. While this method gives excellent results for long threads such as nuts for roller bearing housing, etc., it is open to the objection that for every cut the tool must be moved back to its starting place by means of a reversed belt or else the tool must be removed from bar."

COMPRESSED AIR SYSTEM

Continued from page 28

...s, air hammers, drills, etc., the consumption of which will be, say, ... feet of free air per minute. In ...ing this figure, we must take the ...number of tools that may be ...at one time, as it is impossible ...ion any number of them being ...at the same time.

...dition we have to provide air for ...by 24 inch and a 16 by 36 inch ...hammer. First we must estimate ...consumption of air of the hammers, ...assuming that they will make ...blows per minute (sixty strokes), ...working, and that air is admitted ...two-thirds of the stroke (a hammer ...ion completes a full stroke), we ...equire

...× × 2/3 × 60 = 60 cubic feet ...the small hammer.

1.396 × 3 × 2/3 × 60 = 148 cubic feet for the large hammer.

Total 208

Further assuming that the hammers are at work for twenty minutes and at rest for forty minutes, the average consumption will be 208 × 1/3 = 70 cubic feet per minute of compressed air for the hammers. The average pressure at the hammers being ninety pounds, the equivalent in free air will be 60 times 70, or 240 cubic feet of free air per minute. Adding to this the 300 cubic feet used by the small tools, we find that the compressor must have a capacity of at least 720 cubic feet of free air per minute. Adding about two-thirds to this for safety, we decide on a compressor of a capacity of 1,200 cubic feet per minute free air. Converting this into compressed air at 90 pounds pressure, we have a delivery of 200 cubic feet per minute. At that pressure the small tools will consume 300/6 = 50 cubic feet per minute.

The small hammer 60
The large hammer 148

Total 258

We note from this that the compressor will handle, without calling on the receiver, all the small tools, and either one of the hammers alone, but is 58 cubic feet per minute short of being able to handle all the tools running together.

Obviously the worst condition will be, when both hammers start working together, which condition we have agreed will not last for more than twenty minutes, if both should start a heat together and work for the maximum period. The condition to be met can be most clearly understood by showing the factors graphically, as in the accompanying chart. The heavy full lines indicate the consumption of air by the various tools, the vertical ordinates representing cubic feet of compressed air per minute, and the horizontal ordinates an elapsed time of one hour. The dotted line represents the available delivery from the compressor, which when the demand is less than the capacity of the compressor, will be 1,200 × 15/100 = 180 cubic feet per minute. But, as pointed out before, whenever by reason of the demand exceeding the supply from the compressor, the pressure in the receiver falls, this output will increase, until when the pressure in the receiver has fallen to 80 pounds, it will become 1,200 × 15/80 = 225 cubic feet per minute. This is indicated in the chart by the rising dotted line.

The quantity of air to be supplied by the receiver, during the peak load, will be that represented by the shaded area in the chart, and is at the rate of 258 —180 = 78 cubic feet per minute, at the beginning of the twenty minute period, and 258 —225 = 33 cubic feet per minute at the end of that period. The total cubic feet of air will be the average of these two, multiplied by the time, viz., twenty minutes, or

$$\frac{78+33}{2} \times 20 = 1{,}110 \text{ cubic feet.}$$

As calculated above, for the range of pressures of twenty pounds, the reservoir capacity of the receiver is 0.174 of its cubic contents, and therefore the total cubic capacity of the receiver must be

$$\frac{1{,}110}{0.174} = 6{,}380 \text{ cubic feet.}$$

This demands a receiver about twelve feet diameter by fifty-five feet long, which is undoubtedly much larger than would be usually used. The example is probably a rather extreme case, but was taken as a good example of the saving effected by using a large reservoir receiver. In this case the alternative was to purchase a compressor having a capacity of at least 1,720 cubic feet, instead of 1,200.

TRAINING OPERATORS.

"The importance of the training of operators for both gas and electric welding cannot be overestimated," says Mr. Spraragen, chairman of the American Bureau of Welding. "A very large number of welding experts regard it by far as the most important problem. Widely different ideas as to the proper procedure to follow in the training of welding operators prevail even among experts. For instance, the time required for the correct training of an operator, as stated by a number of authorities, varies from three weeks to two years. Nor is there any greater agreement of the opinions as to what the training should include. Some say that the rudiments of a technical education is necessary, while others stoutly maintain that the operator should only be trained in the correct manipulation of the electrode or torch. In nearly every case where welding has been condemned or where severe legislation has been enacted to restrict its use, the case can be traced directly to poor welds made by unqualified operators."

FOR E. J. THOMAS.

Canadian Machinery has received a most unusual request, namely to acquaint the above named gentleman that his friends are worrying about his absence.

They state as follows: "Won't you please write, letting us know where you are. If you are sick or out of work, please come back to your loved ones. We are all worried about you."

The missing gentleman served in the Canadian army, was gassed and wounded, and has been missing since April 1, 1921. Does anyone know about this?

WELDING AND CUTTING

Some of the Possibilities of Fusion Welding

This Process Can Not Only Be Used for Repair Work, But Can Be Applied to the Manufacture of Metal Parts and in Construction Work—Efficiency Is of First Importance.

*By A. S. KINSEY

THE possibilities of the welding of metals by fusion are far greater than expected. It seems but a short time ago that practically only the railroad shop superintendent and his welders were capable of appreciating the value of fusion weld. The process seems to have drifted into existence without a sponsor, and for a number of years it failed to recieve the attention of the man who should have been most seriously concerned—the mechanical engineer. Of course it is easy now for us to appreciate the value of this method of making a weld, and we may wonder at the indifference of the technical man regarding its merits.

There never was any doubt in the mind of some men as to the possibilities of the fusion weld, and now the most encouraging signs are found in the interest displayed by the technical engineer and his ready approval of the process. Important metallurgical principles are introduced when metal is melted for welding, and no one can appreciate this more than the engineer. He finds in the process not only a fine tool for repairs but he already has learned to apply fusion welding to the manufacture of metal parts and in connection work. No modern mechanical process possesses more encouraging possibilities than the welding of metals by fusion. There are good reasons for this. Let us consider some of them.

An ideal condition would be to have all members of structure solid and without a made joint. The best piece of metal is the one of continuous grain, unriveted, unwelded, so that while a joint is a substitute it is well known that in many instances certain mechanical designs and repairs require either soldered, riveted or welded. For strength the choice must be riveted or welded joint. The riveted joint has its points of advantage and in many cases can not be superseded but it will not serve where uniform thickness of the metal of the joint is required, nor is it always to be depended on for tightness where there is breathing action and high pressure.

The welded joint is not of modern conception, the forge weld undoubtedly dates back to the earlier working of metals. However, the other kinds of welds have been in use less than 20 years. All welding is done by either one of two principles, plasticity or fusion. The forge, the electric resistance and the thermit compression welds depend upon plasticity, while the electric arc, the thermit cast and the oxy-acetylene welds employ the principle of fusion. The respective merits of these two methods of making welds are rapidly becoming well understood.

Welding by plasticity has accomplished much. We have but to consider the manufacture of ordinary wrought iron and steel pipe to appreciate the value of the forge plastic weld. The speed and non-oxidizing features of the electric resistance weld also have proved to the greatest advantage, as in the making of steel chain for example.

But the plastic weld is limited in its application and is confined almost entirely to mild steel. The fusio w however, has a broader range of se ness among the metals. Espec ly this true of the oxy-acetylene w which is applicable to mild ste steel, high speed steel, the ne a steels, cast iron, wrought iron, an um, copper, brass, bronze, le zinc, in fact all of the commercia le may be welded by the oxy-a yl torch. Now the possibilities of g fusion weld depends on (1) high strength, (2) ductility, (3) den control of the welders, (5) a method of testing welds.

Tensile Strength

The tensile efficiency of a w based on its thickness being t as that of the base metal. Th iency is of first importance, but not be obtained at the expense ibility, that is the bending and ing qualities of the metal. In t ing of steel, for example, the d is of much importance. Agai cure the proper tensile effici welded metal must be thorougl to the sides of the vee of the ba One of the best ways of securi tensile efficiency, say in mild to use a welding rod of nickle s ing a tensile strength nearly do of the base metal. The result to be a weld of higher tensile than its base metal. Of course ple reinforcing of a weld is practice.

Ductility of Weld

The ductility of a fusion welc larly of steel, must be consi though there now are some w argue that a weld does not nee bending quality. One of the trations of the value of duct steel weld is to be found in t facture of welded steel tubi can be made cheaper than drawn tubing. In order to ob size tubing the practice is to steel in diameters of from 1 t and then cold draw these tul smaller sizes desired, some of ing as low as 5-32 inch outsid with 1-12 inch hole. It is to

FUSION WELDING

At one time only the railroad shop superintendent and his welders were capable of appreciating the value of the fusion weld. At present we realize its benefits, and one of the most encouraging signs is the interest displayed by the technical engineer in this process.

A better control should be kept on welders. We should know exactly what such men are doing. The foreman should be capable of inspecting the work of the welders, and the men themselves should be trained to thoroughly understand the principles of their work. A night school class on the practical metallurgical end of the business would be a good thing.

Fusion welding made its debut in the repair shop but is now used in many manufacturing plants, and the work it has accomplished in the automobile industry is well known..

* The author is professor of Shop Practice, Steven's Institute of Technology, and presented this matter before the Cleveland section of the American Welding Society.

that this tubing has an oxy-acetylene fusion weld along its full length of many feet which must be capable of withstanding the strain of repeated cold drawing as the large tube is reduced to the smaller diameter. The weld not only withstands this treatment but also is found to be ductile enough to successfully stand being flattened, crushed, knurled or bended. The welding of the large size tube is done at the rate of from 3 to 5 feet per minute with multiple tips in an automatic machine.

Porosity

One trouble with welds has been the lack of homogeniety of the welded metal, and usually the trouble is due to oxides. This applies to all methods of welding but probably less trouble is experienced with the oxy-acetylene weld. In most cases the weld must be absolutely nonporous and the density of its metal should be equal to that of the base metal. A fine illustration of what may be accomplished in this direction may be found in some recent designs of electric sterilizing transformers. In this type of transformer a high voltage terminal is filled with a combination of helium and nitrogen gasses held at a constant pressure of 150 pounds to serve as gaseous dielectric. Of course it is necessary for the pressure of the gas to be maintained constant and therefore the welded joints of the transformers must not allow the gas to leak away. Many attempts were made to weld these transformers but the welds proved to be so porous that the gas pressure could not be maintained until the oxy-acetylene process was brought into use. This has proved highly satisfactory and the elimination of oxides has been so complete that the weld is absolutely nonporous so far as the use of gas at high pressure is concerned. Other evidences of the nonporosity of the fusion weld may be found in its use in refrigerating systems where anhydrous ammonia plays an important part. In this case the weld must withstand high pungent gas pressures and be absolutely tight. The oxy-acetylene weld has been very successful in this regard.

Control of Welders

There must be a better control of welders. We must know more exactly what these men are doing in all of their work. Much attention is being given to this problem at the present time by the American Welding Society. One plan discussed is to require the shop foreman employing welders to have a thorough knowledge of the possibilities of the art so that he may be capable of inspecting the work of the welders from time to time just as he is familiar with and can pass on the work of other mechanics in the shop. The welders themselves should be trained to thoroughly understand the principles of their work by giving them, say, an evening course in the practical metallurgy of the subject. With these precautions, and assuming the men to be of average intelligence and dependability the danger of poor welds should be greatly diminished. Many oxy-acetylene welding schools are springing up over the country and they will undoubtedly accomplish much good in this direction. There is another plan for controlling welders which is being considered carefully and undoubtedly will meet with much success. We speak of the testing of welds.

Testing of Welds

A number of ideas have been suggested for the testing of welds. Some shops require their welders to make sample welds each month which are tested and the results posted on a blackboard for all the shop men to read. This has both its advantages and disadvantages. Another plan is to cut out a section of weld, where it is practicable, and examine it for fusion and porosity. If the welder does not know just when his work is to be tested, he is likely to be forced to constant care. We know of some cases where welders are being required, after making a good sized weld, to stamp their initials and the date alongside of the job so that there can be no question as to responsibility for workmanship, if the weld fails. The testing of welds is of vital importance and it will be of interest to many to learn that a special committee of the American Welding Society is devoting considerable attention to the question at the present time.

In the above remarks we have briefly indicated the factors that usually determine the possibilities of fusion welding. Alongside of these may be placed the experience of thousands of repair and manufacturing plants of this country where the application of fusion welding is meeting with almost uninterrupted success and satisfaction. The fusion weld made its debut in the repair shop. It has proved itself of inestimable value in that place. During the past five years, however, it has been gradually expanded to the manufacturing plant where now it is of the greatest value. Its application to the automobile industry is well known.

There was a time when all steel tanks were riveted. Now there are millions of them being made each year with all welded joints. The all-riveted locomotive fire box is now being welded. Intricate castings which formerly it was impossible to make are now cast in part and welded. One of the newest and most interesting applications of the oxy-acetylene process is in the welding of telegraph and telephone wires. Some of the raildoads have started this practice with the idea of eliminating the ordinary twisted splice joint. The results show that the mechanical strength of the joint is often greater than the wire itself and that the conductivity efficiency in some instances is as high as 100 per cent better than the twisted joint. The first cost of the work may be higher than the twisted joint but the increased conductivity and the fact the joint will never have to be made again makes the welding highly preferable.

We might cite many illustrations of the possibilities of fusion welding in manufacturing, but probably what will be of greater interest to you will be to tell you of the success of the oxy-acetylene fusion weld in new alloyed steels. Fine success has been obtained in the experimental welding of steels such as nickel, chromium, tungsten, cobalt and vanadium. The depositing of alloyed steel on cheaper base metal where intense heat and wear are concerned has been successfully accomplished by the oxy-acetylene torch. This is opening up a fine field for fusion welding and making available certain applications of alloyed steels which were not practicable before.

Just as it is not difficult to produce convincing evidence of the value of fusion welding in modern shop practice, so it may not be considered too venturesome to prophesy the future possibilities of the fusion weld. A process which started as a makeshift of mechanics has become a sure right hand method of the technical engineer for the repair and production of machinery whose value is incalculable.

SOME WELDING HINTS.

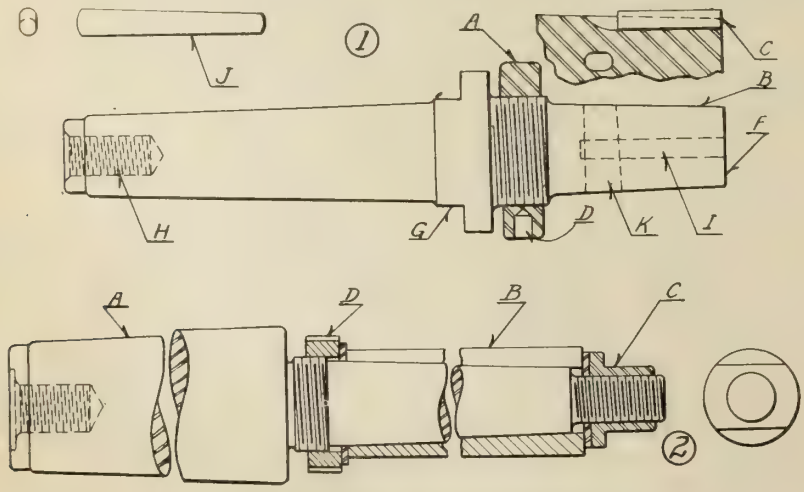
In performing welding jobs, such as on aluminum crankcases, the following kink, given by a writer in the "Journal of Acetylene Welding," can be used to advantage. Often-times is it required to weld a large hole, in which case a chill of galvanized iron is provided, backing up the hole and welding against this when filling the hole with aluminum. Galvanized iron is preferable to any other material, such as tin or iron, since it peels away from the aluminum quite readily, and can therefore easily be removed after the weld has been completed. This is undoubtedly due to the zinc content of the galvanizing composition.

The chief value of the use of the chill is that it causes the filler to cool and harden prematurely, thereby preventing it from contracting after the weld is finished. It also prevents the heat of the weld from spreading, which might cause the job to crack back. The chill is fastened in place by a wrought-iron strap, made in the shape of a boiler crab, which arches the hole. A hole is then drilled through the strap and a similar one through the galanized-iron plate, the two being fastened together by means of a bolt and nut. In making the weld, the metal is first applied to the inner corners and the space filled up by working toward the centre.

Just before the centre is reached, and when it is impossible to add any more metal without touching the bolt, the strap should be loosened, the bolt removed, and the hole filled with the molten metal. Greater success will obtain if the work is done quickly, handling as large an amount of molten aluminum as possible at a time and covering the entire surface of the galvanized chill in a few minutes.

The chill causes the added metal to cool almost as fast as it is connected to the edge of the break. After the weld has been finished and cooled, the chill can be removed by gently prying it away from the weld by means of a cold chisel. The flame of the torch should be kept in motion while performing the work, and should not be pointed toward the weld, but rather across the melting portion; otherwise it is almost certain that the flame will not only injure the metal, but will also burn away the galvanizing if pointed directly toward the weld.

WHAT OUR READERS THINK AND DO

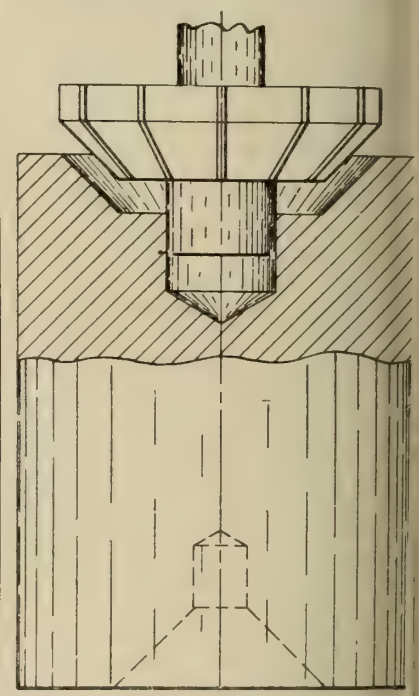


DESIGNING ARBOR FOR WORK REMOVAL

By F. S.

Where a work arbor is permanently attached to a machine it is often advisable to provide some means for forcing the work off after the machining has been performed. Two types of arbors with this end in view are here shown. Fig. 1 shows an arbor used in the tapered hole in a milling machine. The opposite end is intended for holding work with a tapered hole. The work is forced on the tapered diameter B and driven by the key C. The work is removed by means of the collar A, this collar being turned back against the work. In some instances arbors of this character are made with a nut and washer on the end F for forcing the work on the arbor. G is the driving portion of the arbor, the flats fitting into the slot in the milling machine spindle. The front end of this arbor is provided with a small tapered hole for holding small cutters, which are removed by means of a tapered pin driven through the hole K. This may also be used for removing work from the arbor.

The arbor shown in Fig. 2 is used for holding work with a straight bore, the work being placed over the diameter B of the split bushing. The nut C is used for expanding the bushing and holding the work, while the work is removed by action of the nut D—the opposite nut being released when either of the others is being used. These types of arbors may be made to suit any class of work, the dimensions being governed by the size and style of the pieces required.



View showing the two styles of arbors.

SAVING WORN MACHINERY.

The high cost of iron and steel has stimulated engineers to develop efficient means of restoring parts which have become so worn that they are fit only for the scrap heap. A typical example is an engine crankshaft, which after a certain degree of wear, gets out of line to such an extent that it is useless. Welding has been largely used in the work of restoration, fresh iron or steel being welded on to the worn parts, and the whole then made true in a lathe. There are objections to this process in certain cases, and in order to overcome these objections a British engineer has developed a method of depositing nickel on the worn parts. The piece of machinery to be treated is first made free from grease and dipped bodily into a bath of molten wax. After the wax has cooled it is removed from the parts which have to be restored and is left on the others as a protective covering. Cleaning in a bath of acid is followed by immersion in an electro-plating bath which deposits nickel on the exposed surfaces. The coating of nickel is extremely hard, and when the process is properly carried out the nickel adheres with remarkable tenacity to the metal on which it has been deposited. Crank shafts, spindles, axles, pistons and similar objects can be made quite serviceable again by the nickel layer at a cost below that of replacing the whole part. Deposits up to one-eighth of an inch can be applied successfully. It is expected that this process will be developed alongside the welding processes which British engineers have brought to so high a pitch of usefulness in many repairs, such a the mending of cracked or broken cast ings, which could not be handled by th deposition of nickel.

VALVE GRINDING

How much of a valve do you waste grinding it in? The superintendent of a refrigerating plant hit upon a scheme to save valves and seats when they were ground in. In such a plant, valve grinding reaches the stage of a fine art and, as most of the parts are expensive, a saving along this line is worthy of note. The scheme may be seen by observing the drawing. The

plant used the conventional type of valve seat refacing tool for touching worn and pitted seats. Then instead of grinding the valve to a fit in the newly faced seat it was ground down in a false seat made in the end of a piece of soft steel. This false seat was reamed with the seat facing tool and so partook of the same bevel. By wearing down the rough in this false seat, the seat in the valve was saved just that much—and that was saved in an unrenewable part. When the valve looked perfect, it was placed in its final position for a close fitting grinding with its mate. These false seats were made up for all sizes used in the plant.

A Locomotive Punch Press

CAN YOU imagine a locomotive acting as a punch press? During the war, a locomotive was used in such a capacity with great success. According to the story, which is told in the proceedings of the civil engineers' journal of France, the Bordeaux works of the South of France Railway Company, like all other works in France, were called upon at the outbreak of war to adopt a portion of their machinery to the making of "75" shells, starting from steel bars cut to length. These were upset hot in a die and given successively preparatory shapes previous to the final shell shaped form. There was no time to wait for a hydraulic punching or draw down operation, so to save time a powerful locomotive was pressed into service. The engine was moved to a position in front of a stout wall on which the drawing-down die-holder was supported. The locomotive was then raised so that the wheels were clear of the rails, and a punch was fitted to the tail rod of one of the pistons.. A cup was then heated to a red heat and placed in the die. The test being successful, it remained necessary only to make the installation more convenient for use.

This was accomplished as follows: The buffer beam of the ngine was replaced by a much stronger one, built of plates nd sections, and fitted. in front of the cylinder utilized for the lrawing-down operations, with the die-holder, a kind of casing pen at the side for inserting the die. The cups were heated in reverberatory furnace erected close to the locomotive. On eaving the furnace, the base of the cup was slightly cooled by mmersion to a depth of from 2 to 3 centimeters in a tank of vater maintained at a constant level. At the same time, the ottom of the cup was freed of scale by means of a kind of nilling cutter worked by a small portable drilling machine lriven by compressed air, suspended from a jib and maintained t the right level by a counterweight. The cup cooling was so levised as not to water-harden the metal; it merely imparted to t sufficient resistance to prevent the punch from driving hrough the base of the cup. While the cup was being made eady, the man in charge of the punching inserted the first die, luly greased; his assistant then placed the base of the cup in he die, the regulator valve was opened and the punch drove he cup through the die. As soon as the forging had been riven through, the die, which in the process had been raised nd placed exactly in the axis of the cylinder, fell back in its eating and constituted a stop which helped to strip the forging rom the punch as the piston travelled backward. The forging hen fell on a gutter plate, whence it was removed and replaced n the punch when the piston was in the rear position.

The other two passes were accomplished in similar manner nd during the drawing-down operations, the punch was cooled y water jets and the dies were freed of scale, cleaned, greased nd placed in order for each successive operation. The nstallation ran successfully for about two years and produced everal thousands of 75 millimeter shells, pending the putting own of a more suitable hydraulic plant. ,

A New Style of Inducement

THE labor turnover in a printing plant near Chicago is only one-fourth what it used to be according to Frank H. Williams, who tells the story in a recent issue of Industrial Management. A phonograph is the cause of this change for the better. t seems that some six months ago this company installed a egular cabinet size phonograph in the shop. The workers are free to play the phonograph whenever they wish to do so. And ever since it was installed the workers have been sticking to their jobs as no workers in the plant ever did before and they have also been turning out more work and better work than was ever turned out by the plant before.

The phonograph was purchased by the company and by the workers themselves. The plant made the initial payment of $75 on the machine. The remaining sum of $75 still due on the machine was paid by the workers in monthly installments. The sum was raised by the workers paying in a definite sum of money each week to one of their number who in turn, took the payments to the concern from whom the machine was purchased.

In addition to making the initial payment of $75 on the machine, the company bought six records for it when first installed. Since then the company has also purchased other records from time to time.

But the employees wished a greater variety of records and now raise a regular sum of money each week to be used in the purchase of new ones. Also those employees who have phonographs at home bring records to the shop for use during the day.

Mr. Williams goes on to say that the use of the phonograph has unconsciously made the men work faster. Even the president of the company has gone into the shop and watched the workers when the phonograph was not running and again when it was playing some good tune. Without the music the workers plow along at the same old speed. But when the music starts, their fingers fly at a greater speed over the cases and they feed jobs faster than they ever fed them without the music.

The actual monetary value of the phonograph to the shop is a real item, as the manager figures that every time an old men quits and a new man takes his place the cost of this operation is at least $250. This cost comes in slow production by the new man while he becomes accustomed to the shop, in spoiled jobs which every new man is pretty sure to turn out, in jobs which must be reset because they are not set in keeping with the shop's style, and in time spent by the company executives in breaking in the new men. The phonograph has been in continuous use for six months and the interest in it is just as great as when it was first installed.

The Value of Study

SPEAKING on the value of study, L. A. Herbert in the "Service Bulletin.' says that to his mind studying is the greatest opportunity to succeed that the world ever offered to humanity. "If you won't study, you won't learn;" "and if you won't learn—then the other fellow will enjoy the success that would otherwise have been yours.

"Studying should not be viewed as something to pass away the time, but as a serious, important piece of work that concerns your success. Studying gives you the power to accomplish the things that you do not now have the power to accomplish.

"If you don't like to study—but would like to succeed—your position is inconsistent with the proven law of success. Studying is a simple and easy method of making success come quicker. It's like advancing the calendar of your progress several years.

"Studying is the pumping station of knowledge. It enables a man to get full benefit of other men's bought-and-paid-for experiences."

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Any reader who does not receive a scale within one week after his name as winner has been announced, should write us at once so that we can trace the matter up. Look for the winner next issue.

CONTEST OR AUGUST 25TH ISSUE

Contestants are required to write us, stating to which advertisements we refer in this number.

1—Something that runs at 1000 R.P.M.
2 How to successfully waste money.
3 A product that has adjustable cutters.
4—Something small for something big.
5 –Wastes that are occurring unseen.
6—Something that is Canadian Made.
7 A case where special models are developed.
8 Two things that are said to never leak.
9—A product with three protective coatings.
10 A help to transportation development.
11—How to obtain two very essential qualifications.
12 Something that uses no electricity.

As there was no contest in the August 4th issue, we cannot report a correct list of names.

Closing Date for This Contest is Sept. 15th

The Quenching of High Carbon Steels in Water

Are Cracks in Steel Caused Through Two Factors?—Tables Showing Result of Experiments—Rate of Cooling During Quenching—Theory of Quenching—Summary of Points Investigated.

It is a well-known fact that during the quenching of high carbon steels in water, cracks are often formed on their surfaces. The cause is generally believed to be:

1st. The non-uniform distribution of temperature in the specimen during quenching.

2nd. The difference in martensitic expansion of adjacent parts during quenching.

A closer examination of the phenomenon shows, however, that the true cause is not so evident, as the sound due to cracking is often heard some ten seconds after quenching. The thermal stress is maintained so long as the temperature is not uniform throughout the specimen. For instance, in a short cylinder, about 2 centimetres in thickness and height, the difference in temperatures between the interior and exterior parts, during the first stage of the quenching process, may amount to several hundred degrees, and consequently a great stress will result, but after about ten seconds it does not exceed 20 degrees, and hence there is only a small residual stress. Again, at the moment of transformation of austenite into martensite during cooling, considerable expansion in volume occurs. In the case of rapid cooling the transformation does not, however, take place at the same moment at every point within the specimen. Hence a great stress due to unequal martensitic expansion will result which may lead to cracking, although after several seconds, during which the A1 transformation passes over the whole mass, this stress will also vanish.

If the cracks were due to the two causes above-mentioned, why do they not take place during the first stage of quenching, when the specimen is undergoing a large amount of internal stress, and why do they take place after a lapse of time? It is, of course, conceivable that at a very high temperature the material yields to an enormous thermal stress, and therefore this stress is subsequently released, in which case a thermal stress of considerable magnitude may result at room temperature, and may be the cause of the cracks occurring some ten seconds after quenching. The fact that in a high carbon steel, when quenched from a sufficiently high temperature, the cracks are produced immediately after quenching, shows, however, that a greater part of the thermal stress is not released by yielding, otherwise the immediate cracks would not take place at all.

It is a well-known fact that quenching cracks can often be observed in carbon steels or in steels with a small content of other elements, but that it is hardly possible to obtain such cracks in pure metals. These facts lead to the conclusion that the above causes of cracks are not sufficient to account for the observed facts. The present investigation was therefore undertaken to find the real cause of the phenomenon in question.

In order first to show that the cause of quenching cracks is not pure thermal stress, the following experiment was first made: Several cubes, 2 centimetres on each side, were made of steel containing 1.26 per cent. of carbon, and each cube was attached to the end of a thick iron wire, 2 millimetres thick and 30 centimetres long, by means of which it could be placed in the centre of an electric furnace, and be quickly removed for quenching. The furnace was of the resistance type, 25 centimetres long, consisting of a nichrome wire; its temperature was measured by means of a platinum and platinum-rhodium couple. The cubes were quenched in water from different high temepratures, and the quenching temperature at which cracking occurred was observed. If the crack did not occur, the same cube was used twice for quenching, and then renewed; if it cracked, a new one was always substituted.

The following table contains the result of the experiments:

Quenching temperature	680 deg.	700 deg.	750 deg.	770 deg.	800 deg.	820 deg.
Remarks	No Crack	No Crack	No Crack	No Crack	Crack	Crack
Cooling (the specimens first heated to 900 deg., then cooled and quenched).						
Quenching temperature	800 deg.	770 deg.	750 deg.	730 deg.	710 deg.	690 deg.
Remarks	Crack	Crack	Crack	Crack	Crack	No crack

From this table it is seen that during heating the crack does not occur unless the quenching temperature exceeds 800 degrees. During cooling from 900 degrees the quenching crack is always observed down to a temperature of 700 degrees, and not observed at any lower temperature. This limiting temperature is much lower than that during heating. As is well known, the Ar1 point is always lower by about 40 to 80 degrees than the Ac1 point; hence, from the above result of quenching experiments, it may be concluded that during heating or cooling the crack occurs when, and only when, the quenching temperature exceeds the Ac1 or Ar1 point, respectively. Hence the cause of quenching cracks is not pure thermal stress caused by non-uniform distribution of temperature due to rapid cooling, because if such were the case there would be no reason for the cracks occurring beyond the A1 point. The cracks must, therefore, have some connection with the A1 transformation.

In a soft quenching, cracks usually occurred in ten to fifteen seconds after quenching in water; they could be distinctly detected by the sounds accompanying cracking. The same fact also indicates that the thermal stress is not the direct cause of cracking because the cracking occurs after a lapse of time, where a greater part of the thermal stress due to the unequal cooling of the specimen passes off. As is well known, during cooling through the Ar1 point the specimen undergoes a considerable expansion due to the A1 transformation. Since during cooling the outer portion is always at a much lower temperature than the inner portion, the former, during the said transformation, exerts a great impulsive tension on the latter, and this may cause a crack in the specimen. But the fact that cracks often occur after the impulsive stress due to the Ar1 transformation is passed over, shows that the impulsive stress is not the actual cause of quenching cracks.

To get a general idea of the rate of cooling during quenching, a cylindrical piece having the same dimensions was made of the same material as the test specimens. It had two holes bored parallel to its axis and to its middle height, their inner diameter being each 2 millimetres; one hole was bored at its centre and the other just inside the lateral surface. In one experiment a platinum and platinum-rhodium couple was well insulated and inserted into the middle hole, its junction being, however, bare and in direct contact with the specimen, while the other hole was packed with kaolin. In another experiment the couple was inserted into the side hole while the central hole was packed with kaolin. In each case the cooling was measured by a milli-voltmeter with a pivoted needle inserted in the circuit of the couple, the motion of the needle being almost dead beat.

The result of quenching experiments will be next described. The investigation consisted of the measurement of hardness in quenched specimens by means of a Shore scleroscope, the distribution of internal stress being thus found. Four kinds of carbon steel containing the following constituents were chiefly investigated:

No.	Carbon per cent.	Manganese per cent.	Silicon per cent.	Phosphorus per cent.	Sulphur per cent.
1	0.28	0.25	0.42	0.032	0.070
2	0.68	0.51	0.19	0.029	0.027
3	0.91	0.31	0.11	0.027	0.004
4	1.47	0.25	0.34	0.040	0.004

The specimens were tested in the form of a cube, each side being 2.7 centimetres, or a short cylinder, 2.6 centimetres in diameter and in height. On a surface of the cube or the cylinder a narrow hole, about 3 millimetres deep, was bored, and a thick steel wire screwed in, as shown in Fig. 3; this wire served as a holder in the subsequent work. The specimen was placed horizontally in an electric furnace of nichrome wire, and heated to the required temperature. After maintaining the specimen at this temperature for ten minutes, it was quickly taken out of the furnace and dipped vertically into a water or oil bath, followed by a constant stirring, until the temperature of the specimen fell to that of the bath. The specimen thus quenched was polished with emery paper; sometimes it was at first ground with carborundum, care being taken, by dipping it frequently in water, not to heat the specimen too much, since heating may affect the structure and consequently its hardness. The specimen was placed on the platform of a Shore scleroscope, and the position of a point, at which the hardness was to be measured, was read on a section paper pasted on the platform. In the case of the cubes, the number of points by which the hardness was measured amounted to 36, and sometimes more, if necessary. These 36 points were divided into three groups, the outer group consisting of 20 points at the periphery, the inner group 4 points about the centre, and the middle group 12 points situated between these two. In the case of cylindrical specimens, the number of points amounted to 24 in all, the outer group being 12, the middle 8, and the centre 4. In cases when the general character of the distribution of hardness is to be sought, the mean value of hardness in each group was taken. The results of experiments showed that:

(1) In a soft quenching, such as in oil from a temperature not exceeding 820 degrees C., the hardness of different specimens is greatest in the outer portion, and decreases from its periphery towards the centre.

(2) In a medium quenching, such as that of a steel 0.9 per cent. carbon at 780 degrees in water, or that of steel 1.47 per cent. carbon at 900 degrees in oil, hardness is nearly constant everywhere.

(3) In a hard quenching, such as that of steel containing more than 0.68 per cent. carbon from 800 degrees C. or a higher temperature in water, the hardness is least in the outer portion and increases rapidly towards the centre.

(4) When cracking takes place, lines of cracking cut equi-hardness curves almost orthogonally. The form of equi-hardness curves is elongated in a direction normal to the line of cracking.

(5) In the cubes, the equi-hardness lines become roughly circular or elliptical at a short distance from the periphery. The same remark applies naturally to the case of cylindrical specimens.

(6) By grinding away a few millimetres from the surface layer step by step, the irregular deviation of equi-hardness curves from a circle or an ellipse gradually diminishes.

In the present experiment, cracking occurred in most cases, when the temperature of the specimens fell nearly to that of the bath. From the above, the following facts may be inferred:

(7) The hardness does not increase appreciably, so long as the quenching temperature is below the Ac1 point.

(8) When the quenching temperature increases beyond the beginning of the Ac1 range, the hardness rapidly increases, reaches a maximum at about 820 degrees, and afterwards slightly that the hardness of the outer portion decreases. It was found out from curves that the hardness of the outer portion was less than that of the middle portion and that the centre portion was greater than all.

One important fact discovered by the present investigation (3) is that in a hard quenching the outer portion is softer than the inner. This abnormal phenomenon is satisfactorily explained by the theory of quenching put forward by a writer in Science Reports.

According to that theory of quenching, the so-called A1 transformation is not a single, but a compound transformation, consisting of

$$\text{Austenite} \underset{\longleftarrow}{\longrightarrow} \text{martensite} \underset{\longleftarrow}{\longrightarrow} \text{pearlite.}$$

Thus, during a slow or rapid cooling, austenite is at first changed into martensite, which is then transformed into pearlite. During a very rapid cooling, such as a quenching, the change from austenite to martensite is so far retarded that when it is completed the specimen is nearly at room temperature, and therefore the next change from martensite to pearlite cannot progress, owing to the high viscosity of the material at room temperature. During a slow cooling austenite changes into martensite, and the latter, still at a very high temperature, changes immediately into pearlite. During heating, the A1 transformation consists in the reverse change, that is, from pearlite to austenite through martensite.

With regard to the volume per unit of mass, the relation is:

$$\text{Austenite} < \text{martensite} < \text{pearlite};$$

for martensite is known to exist in a more dilated state than austenite, as is seen from the expansion curves at high temperatures. Hence in the A1 range, during slow cooling, the elongation is a differential effect of the expansion due to austenite—>martensite and of the contraction due to martensite—>pearlite; during slow heating, the contraction is a differential effect of the expansion due to pearlite—>martensite and of the contraction due to martensite—>austenite.

In quenching experiments, the rates of cooling in the outer and inner portions of the specimen differ considerably from each other. In the outer portion where cooling is very rapid, not only the second change of the A1 transformation—martensite to pearlite—is stopped, but also its first change—austenite to martensite — is partially arrested, so that this portion ocntains a certain amount of austenite intermingled with martensite. In the inner portion the rate of cooling is not so rapid, and hence the austenite is mostly transformed into martensite; but its further transformation into pearlite is arrested. Since the austenitic structure is much softer than the martensitic structure, it is to be expected that the outer portion, containing a greater proportion of austenite than the inner portion, will be softer than this portion.

If the above view be correct, for soft quenching, such as quenching in oil from a moderately high temperature the outer portion may be just fully martensitized, while in the inner portion the transformation from martensite to pearlite is partial. In this case, the outer portion must be harder than the inner portion, as is actually brought out by experiments. In a somewhat harder quenching than in the last case, the outer and inner portions may possess nearly the same hardness. The fact that above 820 degrees the hardness gradually decreases as the quenching temperature increases, is explained by the same theory, that is, by a gradual increase of austenite arrested and mixed in martensite.

Several quenched specimens were examined microscopically to see whether any appreciable decarburization actually occurred; but except narow edges, or at least in portions where hardness was measured, decarburization was negligibly small. Hence the less hardening of the outer portions cannot be explained by decarburization. It is the common experience of smiths that by quenching pieces of steel in water, the edges are much softer than other portions; this fact is usually explained as the effect of decarburization during heating. In many cases, however, it is caused by the arrested austenite during quenching.

The cause of cracking was next investigated in a series of equi-hardness curves for a number of carbon steels with varying percentages of carbon, quenched from varying temperatures. These curves accompanied the original manuscript, but as their reproduction would have been attended with certain difficulties, they have been omitted from the paper, and are filed in the Institute library, where they can be consulted by any member interested in the subject. Since the form of the equi-hardness line was elongated in the direction perpendicular to the line of cracking, it is to be concluded that the martensite development is greatest in the elongated central portion and least in the peripheries; hence the martensitic expansion in the former portion is much greater than

at in the latter portion. The central ortion exerts, therefore, a great tension n both sides, this tension causing the racking of the specimens. This is why nes of cracking are normal to the ongated equi-hardness curves. Since ie difference in the specific volumes for artensitic and austenitic structures ncreases rapidly as the temperature lls, it may be understood why crack-g generally occurs when the tempera-re of the specimen approaches to room mperature.

Having thus far explained the dis-ibution of hardness and crack lines, ie question of how to avoid quenching racks arises. In quenching practice it not necessary to get very great hard-ss, except in the case of cutlery. It also evident from the above investiga-on that to obtain a martensitic struc-re too rapid cooling is unnecessary. order, therefore, that the specimen ay not crack during quenching, but at its hardness be properly developed, ienching must be medium hard, such as ienching in oil from 900 degrees, in hich case the hardness is nearly con-ant throughout the specimen; hence e stress due to the difference in the ructures is small, and consequently acking cannot occur. For a given eel, the quenching temperature of no acking can be experimentally found in e following way: The specimen is ienched in oil from three different tem-ratures, 800, 900, 1,000 degrees, and e hardness at the outer and central rtions is measured. Two curves of rdness-quenching temperature for ese two portions are drawn. The tem-rature corresponding with the inter-ction of these curves is that required; r quenching at that temperature uses nearly equal hardness in the out-le and central portions.

According to the above view, in a hard enched steel some austenite remains transformed at room temperature, at ich this austenite will slowly trans-rm into martensite. On the other nd, at room temperature martensite s a tendency further to be transformed o troostite, but its velocity is much aller than that of austenite—>mar-site just referred to. The conse-ence is that at room temperature a d quenched specimen will slowly in-ase its hardness with lapse of time. test this inference the hardness of a enched specimen was measured from me to time in the usual way, and its ean value plotted against the time er the quenching.

If the quenched specimen be constant-heated at 100 degrees, instead of let-g it remain at room temperature, the ove change from austenite to marten-te will be much accelerated; at the me time the change from martensite troostite will also be accelerated. nce the hardness first increases, aches a maximum, and then slowly creases.

In quenching a large piece of steel e distribution of hardness in the outer layer is exactly the same as in the case so far discussed; but in the innermost portion, where cooling is slow, the micro-structure becomes troostitic, and there-fore the hardness is here considerably smaller.

Summary

The result of the present investiga-tion may be summarized as follows:

1. In a quenched steel a certain amount of austenite is generally present inter-mingled in martensite. The amount of this austenite increases as the quench-ing temperature increases.

2. In small pieces of steel the per-iphery is harder than the central portion only when the quenching is very soft. In a moderate quenching the hardness is everywhere nearly equal, but in a hard quenching the periphery is always softer than the interior. This anomal-ous phenomenon is explained by the pres-ence of the arrested austenite in mar-tensite.

3. The quenching cracks in small pieces of steel occur when the hardness in the central portion is much greater than in the periphery. The cause of the cracking is attributed to the stress caused by the difference in the specific volumes of austenite and martensite; the specific volume of the former structure being much smaller than that of the lat-ter the central portion exerts a large tangential tension on the periphery, causing thereby the cracking of the specimen.

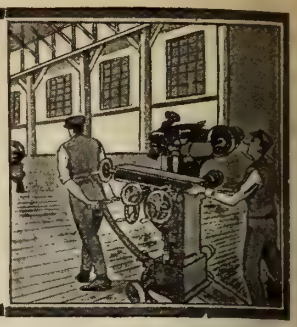
4. Since the difference in the specific volumes increases as the temperature falls, the cracking usually takes place when the temperature of the quenched specimen approaches room temperature.

5. In a hard quenching, the hardness generally increases with the lapse of time, owing to a gradual transforma-tion of the arrested austenite into mar-tensite.

6. In the case of a large specimen, cracking may take place in the A1 range, and also in the vicinity of room temperature. The cracking at the high temperature is chiefly caused by the stress due to the structural difference between the inner and outer portions—pearlite and austenite—just below the A1 point; that at room temperature is due to a similar stress as in the small specimens.

JAPANESE CEMENT INDUSTRY

The remarkable development of the cement industry in Japan is the subject of an interesting article in a recent num-ber of the Weekly Druggist, Tokio. It is pointed out that although the manu-facture of cement in Japan was com-menced in 1880, it was not until 1916 that an export trade was started; but from that date the productive capacity advanced at a rapid rate, until in 1919 it stood at 6½ million barrels, as against only 1¾ million barrels in 1908. The enervating dullness which sapped the energy of Japanese industry generally on the termination of the war had ap-parently little effect on the cement in-dustry. This singular immunity from so comprehensive a depression was preserved by the active promotion of the hydro-electric schemes and of general building and engineering works. The prosperity of the industry naturally res-ulted in the establishment of a number of new concerns. In 1914 the number of cemet manufacturing companies was twelve, with a total investment of 32 million yen, but at the end of 1919 the number increased to more than twenty, with a total investment of over 44½ million yen. The frantic establishment of innumerable businesses, always the concomitant of a boom, was only to be followed by a closing down of these petty concerns on the first signs of in-dustrial depression. As to the future, the article strikes anything but an op-timistic note. The industry at present appears to be suffering from the prevail-ing depression. The war prosperity was evolved rather out of the stoppage of imports from Europe and America than from any inherent qualities which Jap-anese cement might have possessed, so that it is not surprising that the export of cement from Japan should decline with the termination of hostilities and the restoration of industrial capabilities in Europe and America. For the present, the export of cement has not suffered to any appreciable extent as compared with 1919, but that Japan will be able to re-tain the foreign market she had ac-quired during the war is regarded as doubtful.

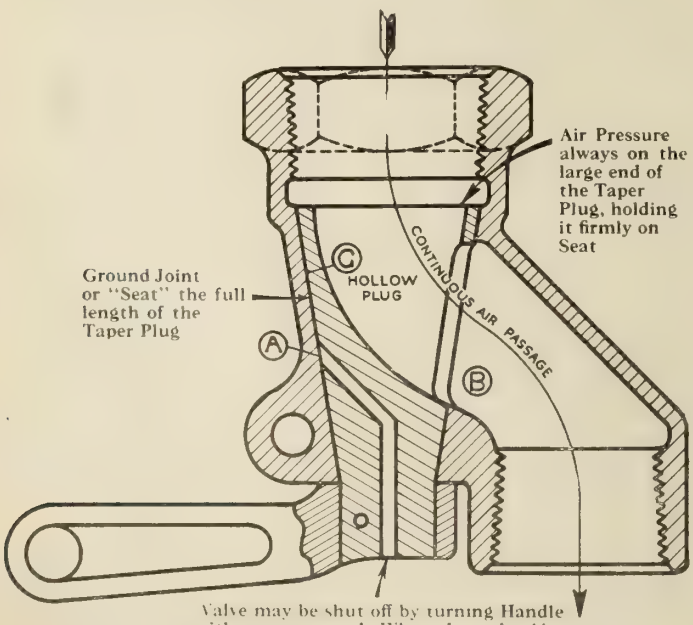


NEW METALLURGIC PROCESS

A process recently invented in Ger-many is said to provide a simple and ef-fective method of separating alloys into their metal components and extracting metals from mineral ores. According to reports, this process will have many advantages over the hitherto employed method of melting alloys and separat-ing the metal components. In this proc-ess the metals treated with the catalytic agents go into solution in a very short time, the treatment of big blocks of metal being effected in less than 30 minutes. Out of the solution thus ob-tained the various metals are dissected by the employment of simple methods of chemical reaction, which permit the re-taining of the metals one by one. The product first obtained is in the form of a muddy sediment which, after being dried, yields a metal powder ready to be used or melted in cruclbles, or to be treated by electrolytic process. Metals and concentrated ores can be treated in the same general way, although they re-quire one or two more operations than pure metal alloys.

The Webster and Perks Tool Co. Springfield, Ohio, have turned over an sold their grinding and polishing stand and accessory department of their bus-iness to the Hill Curtis Co. Kalamaozoo, Mich. The latter Co., at present op-erate a well equipped foundry, forge, machine shop, etc.

DEVELOPMENTS IN SHOP EQUIPMENT



PRESSURE SEATED AIR-VALVE

The Cleveland Pneumatic Tool Co. of Cleveland, Ohio, has recently brought out an air valve for general use in air service which contains new features of great interest to all users of compressed air. The sectional drawing illustrates the new valve.

The destructive action of compressed air upon valve seats, packing and gaskets is well known and there has been for some time a demand by air users for a valve that would stand up in high pressure pneumatic service; in view of the above it was determined to design a valve in which the air could not come in contact with the seat—thus avoiding replacement of seats, and also to utilize the air pressure as a "seating agent" to hold the valve plug on its seat—thus eliminating packing, gaskets, stems and springs and reduce the valve parts to three, i.e., body, plug, and handle.

This was successfully accomplished by using a "hollow taper plug" with the large end uppermost; the air entering at the top, passing through and out of an opening in one side of the hollow plug into the supply chamber which connects directly with the air hose without the air coming in contact at any time with the valve seat—ground joint—which is the outer wall of the plug as indicated by the letter "C" on the drawing. The long "Arrow" shows the direction of the air in its travel through the wide unobstructed air passage of the valve which is free from any angle turns to impede its progress. The short arrow indicates the "point" on the large end of the plug where the air pressure is constant forcing the taper plug against the walls of the valve body forming a perfect seat. The valve is provided with a unique waste arrangement to allow the accumulated pressure in the air hose to escape to atmosphere when the valve is shut off as shown by air ports "A" and "B" on the drawing; this is to safeguard the operator who, when disconnecting the hose from valve often receives a gush of air in the face and accidentally gets scale or grit in his eyes.

This new valve has been subjected to severe service tests under both high and low air pressures, the high being 500 pounds, as well as submerged water tests and has successfully passed the most exacting tests that could be devised on liquids under pressure and on acetylene gas lines.

Sectional View Through Valve

NEW CLEANER

The Hanson & Van Winkle Co., Ltd., Toronto, Canada, have placed on the market a new cleaner called "Roylite." This solution is said to be the latest development in the process of chemicall removing oil, grease, enamel, paint o any kind of dirt from metal efficientl and quickly. It is said to contain cer tain alkali elements which will dissolv animal fat, oil, grease or buffing com positions, and it is claimed that th chemicals do not precipitate, but are a soluble and are held suspended in solu tion indefinitely, this, of course, enablin the use of the bath with less addition

There are various ways in which can be used, but best results are ob tained if the articles are immersed i tanks of hot solution; the hotter th better. Boiling hastens the action, an the chemicals used readily dissolve i water and are instantly ready for us The length of time required for clean ing depends on the nature of the work but it is said that no matter how lon the parts are left in the solution the will not tarnish or discolor.

The use of electric current increase its efficiency, and in some cases the wor can be entirely cleaned in two or thre seconds. After cleaning articles of ste and iron in this material they can b left to dry without fear of rust as th solution prevents oxidation. Followin are a few of its uses:

Cleaning all kinds of metals; remov ing paint, varnish, shellac or japan scouring floors, bottles or any kind o utensil, and any plan where caustic sod potash, lye or similar alkalis can b used. It will not harm the operator hands nor cause any obnoxious fumes.

When it has been used for some tim it may, according to the makers, be re juvenated by merely adding mor cleaner. A case is stated where 50 pounds of this solution cleaned 5,00 rims, or the equivalent to 20,000 squar feet of surface; and at the end of th operation several thousand further rim were cleaned merely by adding 10 pounds more of the cleaner.

FLOOR GRINDING MACHINE

A new design of motor driven grindin machine has been added to the line manufactured by the Marschke Manufa turing Co., of Indianapolis, Ind. It designed for heavy duty with the rota of the motor directly connected to th drive shaft, which is mounted on fou Hess-Bright ball bearings. The contr for the motor is placed in the pedestal o the machine, the operating lever protru ing through the front of the frame. Ma

SURFACE GRINDING MACHINE

An automatic surface grinding machine has been developed and marketed by Wm. Osterhom, consulting engineer, 1301 N. Knox Ave., Chicago, Ill. This new machine is intended for the surfacing of parts in large quantities, and will handle work up to 12x40 in. It is said to handle them rapidly and economically. The machine is fully automatic, with the exception of locating the work and locking it in a suitable fixture which is mounted on the table, being moved across the surface of the abrasive wheel by means of a cam. Upon the completion of the cycle of the cam, the fixture is tilted back 45 degrees away from the wheel, thus allowing the operator to remove the work. Provision is made for varying the length of the stroke, and a change gear box allows for varying the time of the cycle from 10 sec. to 2 min. depending on the work.

The feed of the wheel is automatically controlled by a cam this feeding the wheel gently forward on to the work during the grinding operation. The action of starting the grinding after placing the work in position is accomplished by pulling a handle on the top of the machine, which throws the belt on the tight pulley behind an arresting lever. The sheer drop on the cam releases the arrest lever, and also raises the work to the grinding position. A series of steps on the cam communicates a rotary action to a shaft to drive the wheel housing forward a preconceived distance against the work. A quick return of the lever to its original starting point traps the shifter arrest lever, unlocks the tilting work table and stops the action of the machine. An emergency stop is also provided.

Wear on the wheel is taken care of by means of a graduated handwheel, and a lever adjacent to the change gear box allows the operator to stop the rotation of the cam, but gives free swinging of the work arm, this allowing for the dressing of the wheel.

The machine can be equipped with automatic magazine feed. In this case, two magazines are used, one for receiving and one for delivery. The magazines control the operation of the machine as long as they are properly attended to. If the receiving magazine gets clogged up, the machine will stop, and will, also, if the raw material magazine is emptied up to a certain point. This method of grinding is adaptable to such work as facing of thin, hardened pieces of steel up to 6x6 in., thrust washers, and anything that can be handled and magazined properly. The plain grinding machine is recommended by the maker on such grinding as manifolds and housings where a 2-minute grinding cycle is used, one operator handling four machines. A cylinder wheel, 20 in. in diameter, 8 in. thick and having a 10-in. hole, is used. The weight of the machine is 7,800 lbs., and 20 h.p. is required when working at full capacity.

COMPARATOR DIAL

The B. C. Ames Co., Waltham, Mass., have developed and marketed a device which is intended for use in manufacturing plants on production work, as well as in the inspection department. This device is known as a comparator dial, and all parts are protected from dust and all bearing surfaces hardened and ground. The gage is adapted to use on most work ordinarily checked by micrometers, but the gaging pressure is controlled by a spring. The dial is 1 7-8 in. in diameter. A movement of 0.0005 in. at the measuring point appears at 1-16 in. on the dial. The point has a travel of ¼ in. so that although the gauge be set to a 0.5000 in. standard it will measure from 0.5000 to 0.750 in. The gage is useful on shafts or bushings having more than one diameter of nearly the same size. A stop is furnished for positioning round work. The device is furnished with two anvils, one 1-2x2 in. and the other 2x2 in. and scored. It stands 10 1-2 in. high, weighs 10 lb. and is finished in black japan.

STRADDLE MILLING MACHINE

The Newton, Machine Tool Works Inc., Philadelphia, Pa., have placed on the market a straddle milling machine, which is known by the trade name Model C-70. This is a specialized machine used for such work as the facing of bearings for crank-shaft of automobile engines, at the same time milling the oil slinger grooves. The feed motion on this machine is obtained by vertical movement of the table, and the loading and unloading is done at the top of the stroke. The spindle carrying the cutters does not change its position. The table of machine is raised and lowered by a cam providing slow feed and a quick return. The cutter mandrel is driven from both ends and is supported between cutters by bearings this preventing the tendency to buckle. Spacing collars are provided to hold the proper dimensions between the cutters these giving variation of 0.002 in. The machines can be equipped with a different number of cutters.

BUTT WELDING MACHINE

The Winfield Electric Welding Machine Co. Warren, Ohio, have marketed a butt welding machine known to the trade as Type B 6. This machine is self-contained and is intended for flash welding high-steel drills, handling ¼ to ¾ in. in diameter. A 15-kw. transformer and a 6-step self-contained regulator are provided. The lower dies are copper and the upper dies tool steel. Water circulates through all copper terminals.

Dies located at the front of the machine clamp the work and a single toggle hand lever is used to upset the weld. It is said that the machine is so constructed that the small particles formed by the flash cannot get into the bearings and moveable parts. The machine occupies a floor space of 42x40 in., the height of the dies is 36 1-2 in., while the complete weight is approximately 1,000 pounds.

The Care of Belting

IN another portion of this issue will be found an article on "The Care of Belting." If belting received the attention it deserved such an article would be unnecessary, but unfortunately many run away with the idea that belts take care of themselves automatically. The foolishness of such a belief should be self evident to everybody, especially mechanics, but apart from a casual and occasional daub of dressing spread carelessly, the average workman leaves belting to its own devices. Others imagine, that a tight belt is bound to be all right. There is no thought of, perhaps, an uneven drive; the center of the driven shaft being too near to that of the driving shaft, and the one hundred and one things that can make or mar the finest belt produced.

Many a workman has condemned a belt, when he himself was to blame. Our shoes wear out quickly or slowly according to the use, or abuse we give them. In like manner a leather belt, in fact any belt will wear out rapidly if abused. It pays to make sure the pulley is running true, and that the shaft on which the pulley revolves is properly aligned. When selecting a belt do not consider first cost only. Service, not first cost, is what counts. It is much better to pay a little more for belting, than to buy a poorer grade, only to find that in a short time machines have to be shut down until a repair can be made.

This may seem unnecessary advice, but we know that in many factories such advice is very much needed. Here is a case in point. A certain plant, not many miles from the publication offices of this journal had two large main drives, one for each side of the shop. Every month or so, one of these belts would break with a noise like a gun going off, and of course that side of the factory which the belt was driving was idle until a temporary repair could be made. During the night a workman would make a decent repair, that is he would cement the joint, not merely lace it, as was done in the temporary adjustment. This went on for about two years. Nobody seemed to trouble about the breakages, taking them as a matter of course.

A new superintendent came to this plant and shortly after his arrival one of the belts repeated this performance. On examination he noticed the many repair marks. After enquiring how often this occurred, he had the belt temporarily repaired to get the shop running, then sent for some double belting. Things looked rosy until the cost as found to be more than formerly. The superintendent however, pointed out how much money was being lost in wages, not to speak of loss in production. But why go further? He got his double belting and the trouble was over.

Of course a firm of this standing should have known enough to use double belting for such a drive, and they should never have considered the first cost, but the fact remains that they did **not** know, and that they **did** look at the cost side of it. Get away from such a viewpoint, and where you are not sure, ask someone who does know about belting. Manufacturers of belting are only too willing to give advice, without even suggesting their own particular product. When you have found a b that suits you, stick to it. Use a best drive for the purpose discovering a better belting if possible, but until you ha proven the other belt to be equally as good, or better, stick the style that is rendering you good service. Give your be care and they in turn will give you the best of service, if t material is in them.

Lightness and Strength

"IF you can give us a box that will be lighter, yet equa as strong—why go to it, but you'll have to show m These words were spoken a few weeks ago by a shop super tendent to a salesman who was claiming he could supply bo for this firm's product that would be equal in strength, only half the weight of the style being used.

Nothing daunted the salesman made off with a promise return in a few days with a box that would stand the te When he came, he brought with him a special packer, who he explained, would pack the product as it should be pack Wtih the greatest of care the box was completed, then pass over to the superintendent for inspection.

"It looks fine," was the non-committal remark of the m they must please, then he proceeded, with the help of his m to give the box the treatment it would receive on the ro Inside of three minutes the machine which was contained the box had broken through in two places and the pet dre of the large order for the enthusiastic salesman had vanis into thin air.

"I still believe I can give you a box to suit your purpos finally came from the salesman's lips. "My former answ 'Go to it and show me' holds good," replied the superintend without any malice and off the salesman went to make anot box.

Without question, the weight of packages has been redu considerably within the past few years, but in some ca weight cannot be sacrificed without reducing the streng Reinforcement may be all right in some instances, but wh lugs and other heavy sharp points stick out, good heavy l ber seems to be the safest plan. Had the above scheme b successful the salesman would not only have landed a r order, but the firm spoken of would have saved over $8, yearly in the cost of boxes alone, not to speak of the frei charges, the larger number of machines possible to be pac in a car and so on. Everybody would have benefited, but this case reinforcement, with lighter lumber, did not fill bill.

The Cause of Accidents

In analyzing the reports of 1,000 accidents in the pet leum industry, it was found that over 31 per cent. were to workers being struck by falling objects; 10 per c by improper use of hand tools; nearly 9 per cent. by r falling and tripping; 8 per cent. by men being struck passing objects, and about 4 per cent. by stepping on nails.

MARKET DEVELOPMENTS

Feeling of Confidence Returning to Market

Improvement Continues Although Gradual—Freight Rates In States May Drop Soon—Slight Increase in Steel Demand—Machine Tool Situation Looks Better—Boiler Tubes Take Sudden Drop.

THE market situation is certainly improving. While the movement may be slow, it is sure and there is a decided feeling of confidence coming into the market which speaks well for the future.

The demand upon the steel industry continues, and it is expected to grow in volume as time goes by. Pig iron prices have stiffened, and although these have yet to be tested, no decline later is looked for. In fact everybody has got the feeling that the bottom has not only been reached, but that it has been severely scraped. Dealers are optimistic as to the future and feel the worst has been safely passed.

Machine tool dealers have much to look forward to. The keen competition existing between automobile manufacturers, coupled with the lower prices, means that these manufacturers must look for the quickest and most economical production method. Dealers are being consulted in an advisory capacity, and if they toe the mark, as they should be able to do, suggesting the best machines for the various operations, good business should result.

Small tools continue to move, but very slowly. A few firms are re-opening after a three or four months closure, so that this branch of the market should show improvement soon.

Taken in all there is much to be thankful for, as both dealers and buyers are beginning to realize that many lines are down to practically 1914 levels and cannot drop further. Buyers are at last showing a tendency to purchase for purposes of stocking up.

IMPROVEMENT IN MARKET CONTINUES FREIGHT RATES MAY BE REVISED SOON

PITTSBURGH, August 25.—There is a continuance of the slow improvement in iron and steel conditions. To some this improvement may be disappointingly slow, but a great many in the trade are quite satisfied for there to be any continued improvement at all, seeing that everything has been on the down grade for nearly a year and any turn at all however slight would be welcome.

So much trust might easily be put in the price advances a number of pig iron producers have announced, as the advanced prices still have to be tested, but certainly the pig iron market is much improved when producers are at any rate trying to advance prices instead of putting them down as they were doing for about ten months. The price advancing movement began in the Chicago district, and the Inland Steel Company is commonly given credit for starting this. At any rate while actual sales of foundry ironware recently made at $18, f.o.b. Chicago furnace the regular asking price there at present is $20. The Manning and Shenango valley furnacemen took up the idea promptly, and began announcing an advance in basic iron from $18 to $20. Foundry iron had been $19 valley, and some have announced an advance to $20.50, but that is not general. Bessemer, which had been $20, valley, remains at this figure, and a sale of 10 tons has just been made at the price. Basic iron presented the case that need first attention. There have been no sales in the Valley-Pittsburgh market at the advanced prices, but since the advances in basic were announced there have been no sales at the old price either. There has simply been no inquiry for a while, and there is none just at the moment.

The possibility has developed that freight rates on the materials that have to be assembled to make pig iron will be revised by October rather than in December or January as was the recent expectation, but the matter is in doubt. The furnacemen do not seem to be applying much pressure to the railroads, while the Interstate Commerce Commission is doing nothing, beyond having allowed it to become known that it would approve any reductions the railroads may propose. The expectation is the reductions will be about 20 per cent, when made. The freight assembly cost at valley furnaces of the ore, coke and limestone needed to make a ton of pig iron is fully $10, against not over $5 in 1914. A 20 per cent reduction straight through would therefore deduct $2 from the cost of making pig iron. Furnacemen claim that even with a $20 price on pig iron such a freight rate reduction is already discounted. There is some question, however, whether that is correct. The low point in pig iron was in the early months of 1915, when basic pig iron was $12.50, valley, and foundry iron $12.75. Coke at ovens is about $1.25 higher, the cost of producing iron ore and limestone is higher and the wage cost at blast furnaces is higher, while with a twenty per cent reduction in freights the increased freight cost on raw materials would be about $3. It is quite possible that all the increases together, added to $12.50 or $12.75 would make about $20, and it is universally admitted that when pig iron sold in 1915 at $12.50 or $12.75 the furnaces were doing no more than break even if indeed they were doing that. Eastern Pennsylvania has shown no advance in pig iron and indeed there has been no little decline within the past fortnight. However, the general feeling among pig iron producers is that pig iron ought to advance and as stocks have been very considerably reduced the furnaces may be able to put their views into operation.

There has been only a slight increase in steel demand in the past week, but there seems to be no question that there has been some, particularly in sheets, bars and the tubular goods. The sheet mills as a whole are operating at 35 or 40 per cent, while the pipe mills are probably averaging above 30 per cent, there being a very decided increase thus shown as compared with operations at the middle of July.

There is heavy demand for galvanized sheets for repairing car roofs and little demand for other items of car repair. Otherwise the railroads are doing practically nothing in the buying line. The financing scheme for the railroads, whereby the Government is to provide funds of about $500,000,000, has been encountering much opposition in Congress and while it will doubtless go

through the railroads may not get any relief at all until late in the year. The money would be used first to pay debts and perhaps next to take out more rails, against the contracts made for this year, while next there might be some buying of equipment or improvement in other directions.

Construction projects are still being held in abeyance very largely. Everyone seems to have his own guess as to when and how business conditions will experience any great improvement. The improvement now progressing in the iron and steel industry is of course recovery from a special depression caused by stocks of steel and steel manufactures that had to be distributed. The demand upon the mills is still quite below a normal relation to the present volume of business generally, so that improvement in steel can continue for some time even without general business improving.

Mill Operations

The rate of steel ingot production is probably up by this time to a rate of 25 per cent of capacity, and that is some gain since the average rate in July was only about 21 per cent and at the middle of July the rate was lower still, probably 18 or 19 per cent. Some shipments are being made of stocks of finished steel at mills and some semi-finished steel in stock is being rolled, so that shipments of finished steel have increased in somewhat greater ratio than has the production of ingots.

The expected wage reduction of the Steel Corporation was announced last Saturday, to be effective Monday, August 29. The common labor rate is reduced from 37 cents to 30 cents an hour, other rates being adjusted in keeping. It has been certain ever since the last of the independents got down to a 30-cent rate, in the latter part of July, that the corporation would make this reduction. Some of the independents are paying 27 cents and some 25 cents, but 30 cents seems to have the claim to be the standard. The Steel Corporation has had a policy of lagging behind the independents in both wage reductions and price reductions. The corporation's wage reduction will probably have a good sentimental influence on the steel market, as it has been known that some buyers of steel held that they could not have confidence in steel prices as long as mills were paying higher wages than they needed to pay.

Steel Prices

We quote blue annealed sheets in ordinary sized lots at 2.25c against 2.40c formerly quoted, and note that hoops can often be gotten at 2.30c, particularly from strip mills, against 2.40c formerly quotable. Rivets are softer, 2.35c having been done on structural rivets. Otherwise the steel market has declined in the past week or indeed since August 1. Considering wage rates, freight rates and other items of cost present steel prices are practically as low as were the prices at the end of 1914, they having been the lowest since 1898. While the steel mills have claimed this for several weeks it is only now that buyers are showing any signs of believing the claim.

POINTS IN WEEK'S MARKETING NOTES

A slow improvement continues in the iron and steel industry. Pig iron prices have stiffened somewhat, but too much trust cannot be put in them as they have still to be tested. One fact remains sure however, the market is much improved.

It is likely that the revision of freight rates on the materials that have to be assembled to make pig iron will take place on October 1st, rather than in December or January. This change is not certain, but rumors are abroad to that effect. It is expected that the reduction will be about 20 per cent. This reduction would deduct $2 from the cost of making pig iron.

There has been a slight increase in steel demand during the past week. Sheets, bars, and tubular goods have been especially active. A heavy demand exists for galvanized sheets for repairing car roofs, and a small demand for other items in car repair. Otherwise railroads are doing practically nothing in the buying line.

Machine tool sales are fairly well scattered, but shop executives have become more interested and will now talk to dealers, especially regarding production methods. This condition is largely due to the keen competition among automobile plants, and as one dealer puts it, "They realize they must get the best method of producing if they are going to stand the pace."

The small tool market still shows that purchasers are buying for actual wants only. Prices are being shaved where there is anything like a good order coming. Some dealers are looking forward to increased business shortly as several plants have opened up after a closure of three or four months.

A tendency to purchase for stock purposes has arisen. As one dealer puts it "Many of us are convinced the market in a good many lines has gone the limit so far as declines are concerned." In some cases dealers are not allowing the buyers to dominate the market, stating a price, then letting that remain as a final quotation.

There has been quite a drop in boiler tubes. Some of the yards are carrying very heavy stocks, and it is expected that they will clear this stock out as soon as possible.

HUGE GAS HOLDER IS BEING ERECTEI

Hamilton, Ont., is to be the home o a huge gas holder which is being erect ed for the United Gas and Fuel Co. Th tank will be capable of containing fiv million cubic feet of gas, and effort are being made to have it finished b the first of December.

Special equipment and specially train ed men are necessary on this type o work, and the foundation for the struct ure is a circular platform of cement o the same circumference as the holder it self.

On the concrete foundation is lai the steel floor, which is made of man steel plates riveted together. 60,00 rivets are required to fasten the plate of the bottom together alone. When th bottom sheet was riveted it had to b raised about three feet into the air i order that the riveters might work mo easily. After the job was completed, th great area of steel was lowered to i resting place on the concrete by mea of 144 screws which between them su ported the weight of 250 tons of ste Between the steel and concrete is a th bed of sand to give even support to th bottom and prevent the weight fro resting on the rivet heads alone.

The outer plates of the big tank a built up to a height of 32 feet 4 inche Each plate is curved, and is 26 feet length, 59 inches wide, and the first ri weighs 3½ tons. This is the weight the first of the seven ring plates, a the weight of the other six varies they go higher, becoming less as th go higher. Inside the first circle of st are five smaller rings, or "lifts," son what lighter in construction, each o 16½ inches inside the other. The in "lift" is covered over by the big st crown constituting the top of the c tainer. The first or inner "lift" is feet in diameter, and 30 feet 10 inc in height. The second is 202 feet 9 inc in diameret and 31 feet 6 inches height; the third, 205 feet 6 inches diameter and the same in height; fourth, 208 feet 3 inches by 31 feet inches, and the outer lift 211 feet 32 feet.

Some interesting equipment is be uesd in the constructional work. One table machine is a "bull" riveter, wh weighs nine tons, and is capable of d ing 1⅝-inch rivets cold. The machi used for driving the smaller rivets capable of driving 25,000 a day.

To construct the big "lifts," a "t with revolving arms is erected in middle of the base of the tank, and sides built up by means of this appa tus, which is fed with material by a crane.

The gas enters the holder throug tunnel underneath the concrete fo ation, and is forced into the inner or shell through a pipe. It is colle over the water in the tank till the ho is extended to its fullest height.

DEALERS FIND SHOP EXECUTIVES MORE READY TO TALK BUSINESS WITH THEM

Special to Canadian Machinery

TORONTO—Although there is not enough improvement in the market as week to warrant the assumption at trade has taken a decided turn for e better, one can readily find indica- s and opinions that there has been me improvement.

Machine tool sales have not materially proved—in fact they are still fairly ell scattered, and in small lots. But ere are some shops that have become terested to the point of expressing willingness to have demonstrations ven in their works, especially in cases ere shops are interested in production thods.

"The automobile shops in particular alize," stated one dealer, "that with e new prices of cars and the increasing mpetition in the selling of them, and th the very large number of used rs offering, they must get the very st in the matter of production if they e going to stand the pace. Every op- ation that can be improved upon must changed, and there is on small amount study being given to this matter right w. The result is that the machine tool der and especially the one who can cuss mechanical details from the en- neering point of view, is having his ance to talk things over with the ex- utives now, and there are prospects business. I know of one shop that is conducting experiments in the mak- of fly wheels and other parts, and if se turn out as expected it may mean scrapping of equipment that was ght only a short time ago."

This same dealer also stated that e was quite a difference in the at- tude of the buyers. "Even two months a or less," he claimed "it was a hard tter for a machine man to get a good aring with any of the firms, but there been quite a change in this attitude, a we take it to be one of the indica- ns that the turn in the road is com- ir."

Small Sales Reported

rders coming into the small tool rket are still indicative of buying for tual wants only. There have been no portant changes in the prices named ring the last few weeks, but one has to make many inquiries around the all tool market before finding out n prices are being shaved every time ere is anything like a good order com- out. Reports have it that several ms are considering starting again— ne of them having been closed down the last three or four months. Some the dealers, who were formerly pretty ll "in" on this business, are looking ward to increasing business as a re- su

Liquidation Still in Effect

me of the steel merchants, or the representatives of the larger mills, can give a good answer to the statement that there is no business moving. In this case bookings for the last few days resulted in a fair number of car lot orders, and one of the most significant statements was that some of the business had been placed for filling up some of the stock warehouses.

Inquiries at other places brought the same information, viz., that there was more of a tendency lately to purchase for stock than there has been for some time. Here is the way one of the dealers stated the case: "There is one thing to be thankful for, and that is that many of the dealers are now convinced that the market in a good many lines has gone the limit as far as declines are concerned. The 1914 level is being pretty well approached in many places, and as a result there is going to be some buying done."

Dealers are, in some cases at least, showing less tendency to be dominated by the buyers, and are naming a price and letting that remain as a final quotation.

There has been quite a drop in boiler tubes recently and buying is improving in this line. Some of the yards are carrying very heavy stocks of tubes, and for the next few weeks they are going to have a busy time of it. Of course their best move now is to get cleaned out as far as possible before there is another hitch downward in the market. Forced selling is the one thing that will help clear their stock out, and it is the one thing that will help to make the prices sag a little more.

There is considerable liquidation of stock going on in Toronto, and some of the sales being made are making it evident that prices are not holding firm in some of the lines.

One firm that was getting an exhibit ready for the Toronto fair, remarked on the difference that had taken place during the year. "Just a year ago we took a pile of twelve tons of black sheets and put them in our exhibit at the fair. The second day we were there a buyer came along and wanted to know if they were for sale. We informed him that they were, and he took the lot and never even asked the price. Although the figure today is cut in two it would be a hard matter to set up a pile of sheets and have buyers come along to take them regardless of price."

Nothing Happens Here

"Nothing has happened in the scrap business for some time." Such is the cheering message from one of the larger dealers. "We have been expecting some signs of improvements, but they have not come yet, and we will get them first, you know." This safe dealer some weeks ago drew attention to the fact that any improvement in the whole industrial situation would first of all be reflected in the condition of the scrap metal business. His word was "We get it first when it falls and we get it first when it comes back."

IS THE 75-TON LOCOMOTIVE COMING?

Henry Ford now proposes to revolutionize the locomotive industry. In his first official statement as president of the Detroit, Toledo, and Ironton Railroad, he says that he intends making sweeping improvements in locomotive design. He hopes to reduce the weight of locomotives considerably and in his opinion the present type are about two thirds heavier than necessary, eating up more fuel, and wearing out more rails than they should.

He also intends reducing the weight of freight cars, this in turn reducing the carrying charges. Asked if the 75 ton locomotive of undiminished power was an engineering possibility, he said that it was not only a possibility but that he was going to produce it.

"Storms will not be able to paralyzs railroads in the future" he added "because we will do our train despatching by wireless telephones." Speaking on the moving of freight cars, he claimed that the present movement of such cars was disgraceful. He pointed out that his railroad has increased the average of distance moved from 15.7 to 36.7 miles per 24 hours and he sees no reason why this figure should not be increased to 175 miles every 24 hours.

To show that he means business, Mr. Ford has placed his large staff of designers on the task of creating the 75 ton locomotive. The chemical laboratories are handling the burden of his work for it is upon the steel to be produced by an alloy process, that the hope of a light locomotive is based.

Strength must not be sacrificed for the sake of lightness, and it is the firm belief of those concerned in this development work that the object is to be attained.

TRADE GOSSIP

The next British industries fair will be held in London and Birmingham between the 27th February and 10th March, 1922. This fair is open to manufacturers in all parts of the British Empire and buyers from all over the world are attracted. It affords an excellent medium for bringing manufacturers in direct contact with buyers, as only bona fide manufacturers are permitted to exhibit, and buyers are admitted to the fairs by invitation only. The general public are not admitted. Full details can be obtained from H. M. Trade Commissioners at 248 St. James Street, Montreal, 260 Confederation Life Building, Toronto, or 610 Electric Railway Chambers, Winnipeg.

Building permits issued for new buildings and repairs in Montreal for the month of July, reached a total of $1,560,816.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES

TRADE IN ENGLAND EXPECTED TO IMPROVE SHORTLY. NEW CONCERN FORMED

Work in the engineering trades in England has failed to show any change for the better. F. W. Field, H. M. trade commissioner at Toronto, speaking to Canadian Machinery on the subject, said that according to information received from London, a great deal of short time is being worked in the North and Midland districts.

It seems that in view of the uncertainties of the position with regard to coal and engineering labour, the commercial side of engineering is largely in a state of laissez faire and order books are closed, in spite of the fact that orders may be wanted at any moment. Firms are anxious to get a proper basis on which they can estimate their cost of production before quoting to customers on any contract for delivery of over three months, and the fact that production has been so largely diminished also renders them very chary about filling their books.

In these circumstances it is not surprising that the export figures for May showed a substantial reduction on those for previous months. It will be found, however, that considering all things the figures are really better than might have been expected, and it is anticipated that the first sign of stability in trade and a cessation of the continual labour unrest will soon develop a healthy condition with regard to export trade, and that the export figures will reflect this in no unmistakable manner.

Davy Brothers, Ltd., of Sheffield, have recently opened a new works, and although this extension occurs at a time of industrial depression, it will have its effect when conditions once more become normal. This firm has a large home and overseas business and build a great deal of machinery employed in Sheffield steel works, including the latest types of continuous rolling mill plant, as well as forging presses. Eventually there is to be a complete set of engineering works but for the present the building has been restricted to a series of light machine shops.

Power Presses and Machinery

The formation of many companies into "Nobel Industries, Limited," has resulted in the engineering branch of Kynoch, Ltd., Birmingham, one of the constituent companies, being afforded exceptional experience in special engineering work owing to the engineering requirements of other constituent companies. This special work, in addition to many years' experience in engineering, has tended to produce a department capable of meeting the diverse demands of overseas buyers.

A brief description of the engineering department, as it now exists, is given in order that overseas buyers may judge for themselves the extent to which the engineering department is capable of satisfying the requirements. The drawing office consists of a highly-trained staff of designers and draughtsmen under the control of expert engineers. A laboratory with a staff of metallurgists, who regularly analyse all metals to ensure correct mixtures and advise the most suitable material for different working parts, ensures a high standard of efficiency and durability. The pattern shop is equipped with up-to-date wood working machinery, and patterns of the greatest accuracy are made, including complete gear wheel patterns with true and accurately-pitched teeth. Iron foundries are fully equipped with melting cupolas and high-speed electric cranes. The foundries are divided so that all small castings which require minute attention are made in a specially equipped small foundry, whereas in the large foundry castings of all descriptions can be produced up to 40 tons each. There is also a non-ferrous metal foundry capable of producing castings in brass, gunmetal, phosphor bronze or manganese bronze in all sizes up to 2 cwts. each. The machine shops are well equipped with modern high-speed machine tools for large and small work, with ample electric lifting crane capacity, and possess special gauge and inspection departments to ensure accuracy. Wherever possible, machinery is done to jigs, specially constructed, to secure interchangeability of parts, and all parts are carefully gauged before assembling.

The main line of manufacture is that of power presses, in which Kynoch, Ltd., have had years of technical experience not only in design and manufacture, but also in actual running experience of their own and other well-known makes, which have from time to time been installed for the production of ammunition and other products manufactured in their factories. This enables them to offer power presses and other special machines embodying the latest improvments and refinements, from which have been eliminated deficiencies and weaknesses which have been disco experience.

In addition to presses, suita can be designed and supplied, he ganisation including a staff o in the manufacture of ferrous d ferrous sheet metal articles. range of designs and sizes o presses necessary to meet all h mands of the sheet metal wo dustry cannot be fully descri this concern specialise in the f

Blanking preses for cutting o ing and short drawing; drawing stamping presses of the incli geared and geared type, cam t gle type, and baling presses– ing yarn, hides, skins, hay, h cotton, wool and other materia

AUTOMOBILE INDUS HAS MADE RAPID ST

Export Trade Rapidly Growing Given Denote that Canad Contributed Greatly to Industry

Canada holds second place a countries of the world in p possession of automobile, h proximately one car to every of population. The automobil facturing industry has ma strides in Canada, and at t 1919, the amount invested wa imately $57,000,000. These fig been carefully compiled by th ion Bureau of Statistics, an 1,289 plants in which this ca invested, 1,236 made repairs, duced accessories, whilst 11 e the manufacture of automob tario led in the number of p 639; Quebec 165; Saskatche Alberta 98; Manitoba 84; Br umbia 84; Nova Scotia 49; N wick 34; and Prince Edward I

Ontario was in 1919, the vince manufacturing automo capital investment being $48, which about $35,000,000 was facturing plants. Just how f io has monopolized the indust from the fact that the investn other provinces amounts to than $8,000,000. That of Sas came next with $1,813,002.

The number of employees e the industry was 12,139 of w than one half were employe mobile plants. In the year view they were paid in wage aries the sum of $15,389,000. terials used in Canadian pl

? Who was the Third Man?

WHEN the retirement of Sir Robert Borden as Premier of Canada was first announced, three outstanding men were considered as his possible successors. Their names were displayed prominently in every Canadian newspaper. The present Premier was of course one of the men mentioned. Sir Geo. Foster another. Who was the third man? You would remember him no doubt if his name were displayed prominently in the daily press to-day—but he has retired from the political arena, and his name is seldom mentioned.

How easily names slip from the memory when they cease to be given publicity.

There is a lesson here. If you wish your name and the name of your products to be remembered, you must give them constant publicity.

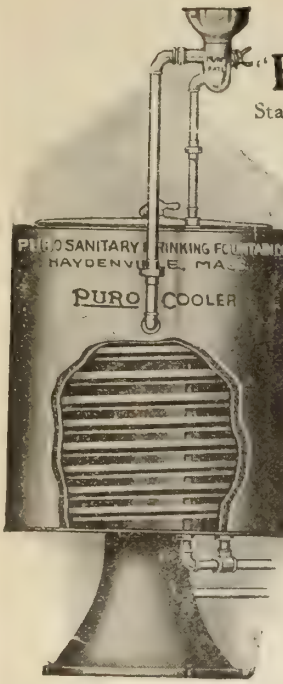
Canadian Machinery

Power House

Canadian Foundryman

Marine Engineering

Each of these technical newspapers is a member of the Canadian National Newspapers and Periodicals Association.



The prudent manufacturer of machine tools, power plant equipment, or industrial supplies of any kind places his name and the name of his products where they will be seen and remembered to best advantage: **in reliable technical newspapers.**

Reliable technical newspapers in Canada are those included as members of Canadian National Newspapers and Periodicals Association. Their circulation is bona-fide and their editorial practice is carefully guarded, in fact their whole policy must conform to the highest standards else they would not be eligible to membership in the association.

Canadian Machinery

valued at $61,279,000, no less than $51,690,715 having been in the manufacture of automobiles. The selling value of the products at the works was $101,196,000 and the number of cars turned out being somewhat over 68,000, there being 21,000 other machines produced.

Export Business

The exporting of automobiles and their parts is also increasing, for whereas the exports in 1915 amounted to only $3,054,000, the figure up to the year ending March 31st, 1921, was $19,628,000. According to reports Australia and New Zealand are the best markets Canada has for cars, whilst the United Kingdom, India, South Africa and the Dutch East Indies also take a goodly number. The United States absorbs a considerable quantity of parts the value of these during the fiscal year 1919-20 amounting in value to $282,000. Altogether 21,128 cars were exported in the fiscal year ending March 1921 as compared with 12,750 in the previous year. The large increase in exports in the past fiscal year is to an extent explained by the coming into effect of the British preferential tariff at the end of 1919 which grants a preference of one-third provided that not less than twenty-five per cent of the labor on the finished car shall have been done within the British Empire.

Windsor and the surrounding communities of Walkerville, Ford City, etc., are the centres of activity, although Toronto, Oshawa, London, Chatham, Kitchener, Hamilton, Brockville, etc., are heavily interested.

TRADE REVIVAL EXPECTED BY FALL

British Manufacturers are Laying Plans For Future. Look for Keen Foreign Competition

British manufacturers expect a trade revival shortly according to "The Empire Mail". In several cases they speak of reorganizing for trade, and following are a few excerpts which show how the wind of industrial activity is blowing. They say that British manufacturers are actively formulating their plans for the future, paying regard not only to manufacturing economy but also to the most effective means of disposing of their goods. The recrudescence of trade, they realise, will be accompanied by the severest foreign competition, and under the handicap of a depreciated foreign exchange. British salesmanship will be taxed to the limit of its capability.

In another case they say that a very substantial improvement is looked for in the near future, and that there seems to be a general agreement among business men that three main obstacles stand in the way of a satisfactory revival of British trade. These are first of all the cost of industrial coal, secondly the crushing weight of taxation, due to the extravagant policy of the Government, and thirdly, the unrest among the workers, and their reluctance to face the inevitability of wage r tions. Trade will never improve a large scale until some means are f of stimulating demand both at hom abroad. A leading expert in the len industry says that market both of raw material and of fin cloth have sunk to below the cos production, and are to-day on a economic basis. The public that now, buys wisely. The same a to a very large number of other tries, and the lesson is plain, na that somehow costs of production be brought down to a level which ables the finished article to be sold price which buyers are prepared t . Wage adjustments have been a recently in a good many trades thr out the country. It is beginnin dawn upon some of the workers h they are likely to sink deeper and er into the mire of unemployme they continue to answer all reques reductions in wages with a stubbo fusal. The progress of their edu in this respect however is not as f it might be.

Confidence Returning

Confidence in the gradual recov British trade is now felt in most industrial centres according to a h statement. The coal peace has b a brighter outlook and the prom lower fuel costs. Wage readjust in some industries have also been ed, so that manufacturing costs v lessened and manufacturers will b to cheapen prices and at the sam more effectively counter foreign c tition. The improved prospects a flected by a greater volume of in from overseas, and fresh orders a ing booked, particularly in Sh Birmingham and the West of E

Trade Gossip

Major Chisholm, Canadian Trade missioner in Cuba, is in Canada a be available for consultation an after August 25. Major Chisholm i making a tour of Ontario, Quebe the Maritime provinces before re to Havana. Major Chisholm Mexico in the autumn of last ye has just recently completed a tour embraced Jamaica, Venezuela, Co and Panama, being throughly f with the commercial conditions o countries.

A factory in Argentina is b marine gasoline and oil engine factory, which is the only one of i in the neighborhood, produces 15 per month, varying in size from h. p. The engines are of the t four cylinder type, and are said modelled after English pattern steel is imported from England, a motors are sold direct to local boa builders.

Trade Gossip

A'd and Co. Toronto, are making an addition to their worsted spinning plant. This new building will be 107 ft. by 82 ft., and will be of fire proof structure, built of reinforced concrete, steel sash, wire glass, etc. Three stories are going to be erected, and although the building will be completed around the end of August, or the middle of September, the work in the new addition will not be commenced until the first of next year.

* * *

The Beveridge Paper Co., Montreal, have changed their name to the Beveridge Supply Co. The reason for the change is said to be the fact that for several years they have been running a supply department, and therefore feel that the word "Paper" does not sufficiently indicate the nature of their business.

* * *

The Refinite Co., of Canada, who have been incorporated, have established headquarters at 319 Continental Life Building, Toronto. Mr. E. G. Koyl is in active management of the business. This company have acquired all Canadian rights to Refinite and Booth water softening systems, and Refinite rapid pressure filters. As far as possible, the devices made in Canada, and Canadian materials are purchased for the making of the same.

* * *

The Abitibi Power and Paper Co. have started three additional newsprint machines, one of which is already in operation, this bringing the daily newsprint output up to well over 300 tons. When these additions are all in operation the daily production will be over 500 tons.

* * *

St. Ambroise de Chicoutimi, Inc., is about to erect a steel bridge costing about $20,000.

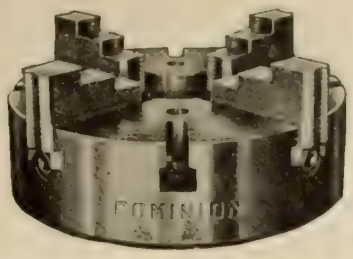
* * *

Considerable work is being done on new buildings in Montreal at present. About half of it is repair and alteration work, where over $50,000 is being expended.

* * *

Improvements and studio are planned by W. R. Barefoot, 1196 Bloor St. W., Toronto, these to cost around $15,000.

* * *



Last month, blast furnace A of the Ford Motor Co., Dearborn, Mich., broke all previous records for tonnage and coke consumed per ton of iron. Here are the figures:—Average tons per day, 509.8; coke per ton of iron, 1,981 lbs.; average silicon, 2.85 per cent; average sulphur, 0.03.

* * *

The Rolls-Royce Co., of America, East Springfield, Mass., have closed their plant until Sept. 6.

* * *

The production of soft coal in the United States is the lowest it has been in twelve years. The output for July is considerably below that of the month of June.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

STEAM ENGINES.

No. 321—1,000 H.P. International C. C Steam Engine.
No. 353—350 H.P. Porter Allen Steam Engine.
No. 355—1,000 H.P. Tod Reversing Engine.

CRANES

No. 323—Wellman, Seaver & Head Furnace Charger.
No 427—5-ton Whiting Travelling Crane, 48' span.
No. 431—15-ton Whiting Travelling Crane, 72' span.
No. 432—Wellman, Seaver & Head Low-ground Open Hearth Charger.
No. 433—Wellman, Seaver & Head 25-ton Crane, 37' 5" span.
No. 434—Wellman, Seaver & Head 15-ton Crane, 72ft span.

BOILERS AND BOILER EQUIPMENT.

No. 327—Smart Turner 5"x7½"x8" Boiler Feed Pump.
No. 454—Epping Carpenter Duplex Pump, 6" x 4" x 6".
No. 455—2,000 H.P. Cochrane Feed Water Heater
No. 456—500 H.P. Goldie & McCulloch Boiler.
No. 470—250 H.P. Goldie & McCulloch Boiler.
No. 472—100 H.P. Goldie & McCulloch Boiler.

FOUNDRY LADLES.

No. 417—10-ton Ladle.
No 526—20-ton Ladle.
No. 2091—3-ton Ladle.
No. 2093—2-ton Ladle.
No. 2065—Small Ladle, 23" dia. x 22" deep.

METAL TESTING MACHINES.

No. 424—A. W. Tensile, Bending and Compression Testing Machine.
No. 425—Brinell Testing Machine for hardness
No. 426—Scientific Materials Co. Microscopic Photographic Bench.
No. 531—Johansson Precision Blocks, No. 1206
No. 208—A. W. Measuring Bench in 1/10,000"

ELECTRICAL EQUIPMENT.

No. 435—40 K. W. Belt Driven Generator, 550 volts, D.C.
No. 485 to No. 487—300 K.V.A. Can. General Electric Transformers, 22,500 volts to 2,200 volts.
No. 488 to No 493—140 K.W. British Electric Transformers, 22,500 volts to 2,200 volts.
No. 494 to No. 495—350 K.W. Bruce Peebles Motor Convertors, 2,200 volts A.C. to 250 and 500 D.C.
No. 496—375 K. V. A. Steam Driven Generator, Swedish General Electric Co., 2,300 volts, 3 phase, 60 cycles. Complete with engine, exciter set and switchboard.

ELECTRICAL EQUIPMENT (Cont.)

No. 547 to No. 549—25 K. V. A. General Electric Transformers, 2,200/550. volts.
No. 558 to No. 560—250 K. V. A. General Electric Transformers, 22,500/110 volts.
No. 561 to No. 569—500 K. V. A. General Electric Transformers, 22,500/110 volts.

PUMPS.

No. 332—Deane 2⅞"x10" Triplex Hydraulic Pump, Gear-driven.
No. 333 Darling 5"x7"x10" Vacuum Pump.
No. 450 -Bawden 7"x9"x10" Pump.
No. 453 Smart Turner 11½x2¾ 'x4" Pump.
No. 553—March Deep Well Pump, 3' stroke x 8" bore.

STEAM HAMMERS.

No. 335 3-ton Bertram Hammer, Arch Frame
No. 336—1-ton Massey Hammer, Arch Frame.
No. 337 12-cwt. Massey Hammer, Arch Frame
No. 338 8-cwt. Massey Hammer, Arch Frame
No. 339—4-cwt. Massey Hammer, Arch Frame

SHEARS.

No. 349 Craig & Donald Shear, Capacity 3½" to 4".
Noi. 352—Long & Alstatter Shear, Capacity 6"x⅞" M.S.

ELECTRIC FURNACES.

No. 382—3-ton Heroult Furnace.
No. 383—6-ton Heroult Furnace.

MISCELLANEOUS.

No. 181—Amer. Tool Co. Oil Separator, No. 2
No. 187—Noble & Westbrook Stamping Machine.
No. 194—Automatic Machine Co. Threading Machine.
No. 196—Hoefer Tap Threading Machine.
No. 207—No. 2 Greenard Arbor Press.
No. 270 Tilghman & Brooksbank Sandblast.

PLEASE REFER TO MACHINES BY NUMBER

Large Stock of Small Tools, High Speed and Carbon Steels, Motors, Etc., of all sizes, A. C. or D. C. Current

Plant can be viewed at Longueuil Works—Full details on application.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

An Opportunity for Every Exhibition Visitor to See Two Huge Displays ---- of ----

MACHINERY AND SUPPLIES

It Won't Take You a Step Out of Your Way--We'll Be Glad to See You

When you come to Toronto for the Canadian National Exhibition you are cordially invited to visit us.

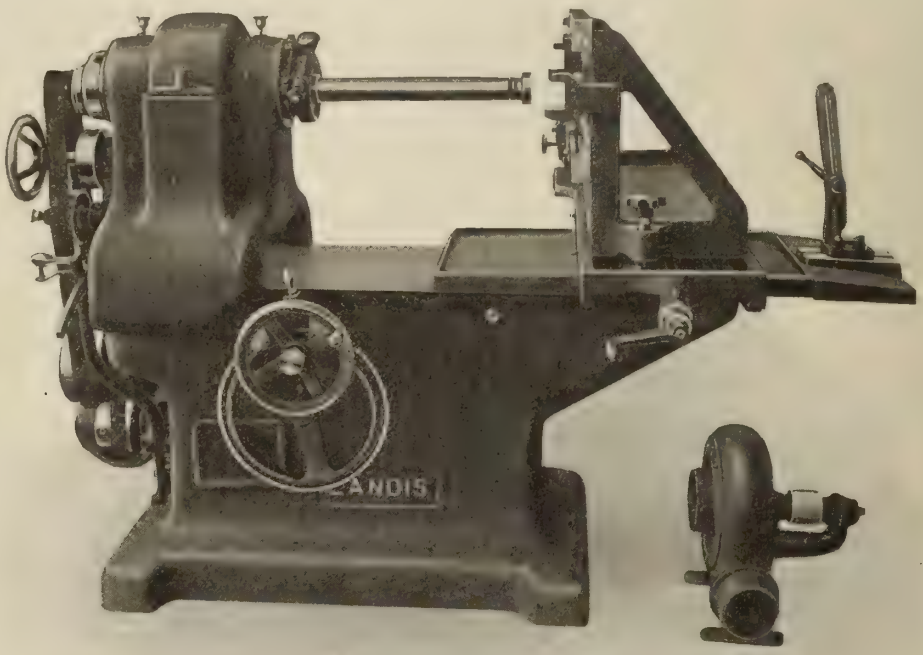
We are not exhibiting at the Exhibition—circumstances have made that impracticable—but our own two warehouses are an "exhibition" in themselves.

Our headquarters and one warehouse is next door to the Union Station. Call when you get off the train. Our other warehouse is at 27 Bathurst St. Cars for the eastern Exhibition entrance pass the doors. This super-structure covers 3½ acres and contains all the newest and best in machine development.

Here's a real chance to examine that new machine tool. Come in, look them over and let Petries' 50 years experience be your guide.

Both of our well-stocked warehouses are directly in line of march to the Exhibition grounds. Cars pass right by the doors. Call and see these mammoth displays of Metal Working and Woodworking machinery.

H. W. PETRIE LIMITED
TORONTO and HAMILTON



PETRIE

A NEW MACHINE FOR REPAIR SHOPS

No. 5 Cylinder Grinding Machine

LANDIS

AN IDEAL TOOL FOR REGRINDING CYLINDER BLOCKS AS WELL AS ODD GRINDING JOBS THAT COME TO REPAIR SHOPS DAILY

This new cylinder grinding machine is rigidly constructed, the main bed being cast in one solid block. The centering device is the exclusive feature. It properly locates the cylinder holes with center of wheel rotation and eliminates the necessity of a knee for vertical adjustment.

The simplicity and ease with which this machine can be operated was not overlooked in the designing, and it requires no skilled operator to turn out a first class job. One hour's time to grind a Ford block is a record that speaks well for the productive qualities of this tool.

Write us for literature immediately.

LANDIS TOOL CO., Waynesboro, Penn.

Heat--Treat With Electricity

Electric heat is economical. Eighty cents of each heat-dollar you spend does useful work in raising the temperature of the steel instead of that of the work room. Electric heat is clean, constant and under hair-line control. Therefore, rejections are almost eliminated and production may be greatly increased. The workman is comfortable and he works on production, instead of fussing with valves. Hoskins Electric Furnaces will lower your heat-treating costs. Send for catalogs No. 121

HRAM WALKER & SONS METAL PRODUCTS LTD.

WALKERVILLE, ONT.

P & W

Pratt & Whitney Taps

"With the 'Con-eccentric' Land"

P & W Taps are **Good** taps—easily the best where accuracy and high speed are essential. They cost more to buy, but less to use than others.

If you're doing work that calls for big production and for unusual precision, give them a trial. You'll be back for more when you see them prove themselves.

The "con-eccentric" land — the special feature of Pratt & Whitney Taps, permits sharpening on face of the cutting edge without affecting size. It lengthens life and assures accuracy hitherto thought impossible in a commercial tool.

8 SIZES

8"x18" to 16"x16"

MODERN
Plain Grinding Machines

Main Drive

The shaft is ground, and mounted on anti-friction bearings; runs at constant speed. Power can be applied from a line shaft or direct from motor. All parts are balanced to eliminate vibration.

Wheel Drive

More powerful than other types of same rating. A 4 in. endless belt carries the full power from main shaft direct to wheel spindle, giving constant smooth drive.

Gear Case

All speeds and feeds are secured from one gear box, a separate unit, which may be readily removed for inspection or renewal of bearings. Gears are in mesh at all times, and are engaged with shaft by our patented positive ball drive clutch, which permits instant change. Gears of steel with hardened bushings run in grease.

Send Us

—Blueprints and specifications, and we'll tell you what a Modern will do on your job.

Motor Drive

A constant speed motor may be attached to the main drive shaft of the machine by belt, silent chain, or flexible coupling.

All Modern Plain Grinders are specially designed for most convenient connection to motor.

Table Drive

This is through worm and worm wheel insuring smooth, uniform travel. Four table feeds, 22 in. to 104 in. per minute are secured by lever on front of machine.

Wheel Slide

Travel is on "V" and "Flat" ways, giving true, accurate movement and long life. A gib prevents raising of slide when heavy cuts are taken.

Bearings

Wheel spindle has bronze bearings with outside taper. Quick take-up for wear without dismounting is provided.

Main drive has anti-friction bearings.

Headstock has ball bearings.

Gear box has phosphor bronze bearings.

All provided with proper lubrication.

All shafts are ground.

An Office Staff of 20 Persons —and no Time Recorder

you could borrow $12,500 for a year on what you lose

—our figures are not built on guess work or theory.

—it is our business to KNOW—

—it has been our business for 30 years to stop cost wastes for governments, railways, factories and business houses.

Minute and careful surveys in thousands of offices prove conclusively that the AVERAGE COST of being without a time recording system is as follows:

In an office employing 20 persons the average loss is 15 minutes per day, per employee. The total daily loss, therefore, is 300 minutes (or 5 hours).

The yearly loss at this rate is 1,500 hours, which figured at 50 cents an hour is $750. At 6 per cent. this $750 would obtain for you the use of $12,500 additional capital for a year.

If you have difficulty in understanding wherein such losses are possible, ask yourself these questions for it is not a problem of ONE leak to stop, but of HUNDREDS. How many employees are 5 to 15 minutes late in the morning? How many take 10 to 20 minutes extra for lunch? How many stroll out a few minutes ahead of time? All for the reason—no place to register their time mechanically.

Perhaps you will say: "But some of my clerks work overtime—at balancing periods, etc." Of course they do. They do in all offices. But what means have you of giving proper credit where credit is due for this work—not perhaps in actual money but in establishing a reserve of merit for the next promotion?

An employer who neglects or refuses to use the International Time Recording System is standing in his own light. He can render justice neither to his own interests nor to those of his employees.

The World's Taskmaster

The world's work of every kind is set by the clock. It is begun by the clock; its progress, step by step, is measured by the clock, and its ultimate value, whether it be finished or unfinished, is fixed by the clock.

The clock takes the measure of all values. For this reason, the records produced by the International Time Systems are the most efficient records in the world. They are written directly, mechanically and unerringly by the steel hands of the World's Taskmaster—the Clock.

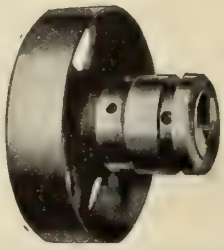
THE JOHNSON FRICTION CLUTCH



It's a Johnson Lineshaft Drive

A battery of twelve light presses, all on a bench about 30 x 5, driven from one lineshaft with Johnson Clutches controlling the machines.

Illustration by courtesy of The New Departure Manufacturing Co., showing bench presses in operation at their Elmwood Plant.

FRICTION CONTROL MEANS BETTER MACHINERY

We specialize in applying the proper type of friction clutch on any sort of an installation. Standard clutches available from stock, and special models developed to suit conditions.

COMPARE IT FOR FIRST COST

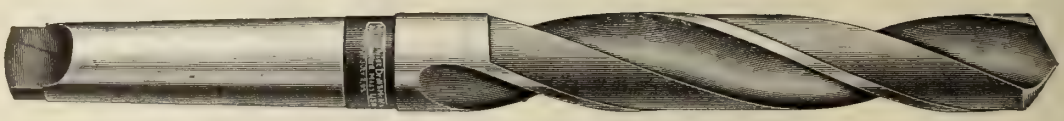
Twelve Clutches against twelve complete counter shafts, or twelve individual motors.

COMPARE IT FOR EFFICIENCY.

Quick, smooth control against the sluggish tight and loose pulley. Or one motor consuming current instead of twelve.

COMPARE IT FOR SERVICE.

You know the failing of belts—the continual attention they require, especially when they are shifted. If you don't know Johnson Clutch Service, just give it a trial.



Write for our booklet

"Clutches As Applied to Machine Building." and our Yellow Catalog.

FORD-SMITH
DISC
Grinders

High-Class Made in Canada Machines

MACHINES which bear a reputation for doing quicker, better work, and whose upkeep expenses are practically nil, merit investigation.

Such machines are Ford-Smith Disc Grinders; every model of the Ford-Smith line—and there's a model for practically every purpose—is designed to give quality production as well as quantity.

Before leaving the factory all Ford-Smith Grinding Machines are subjected to a series of exacting tests, covering every detail of their construction. These tests prove that the mcahine is capable of filling all our claims.

Many manufacturing operations show possibilities of exceptional economies by the use of suitable grinding processes. Have one of our engineers call and see just what saving grinders would effect on your work.

Any information with regard to Ford-Smith Grinders will gladly be furnished.

Send for our latest Disc Grinder Bulletin.

BROWN-BOGGS

B B

Make Sure of the "B-B" Trade-Mark

It is a Guarantee of Reliability

The "B-B" trade mark on power presses, shears, tinsmiths' tools and canners' evaporators, and sheet metal working tools of every description, is an iron-clad guarantee that it will give satisfaction on the work for which it is built. And because every tool before it leaves the factory is rigidly tested, we *know* that its merit is beyond question.

We shall be glad to send you catalogs fully describing those machines in which you are interested.

B B

THE BROWN-BOGGS CO. LIMITED

HAMILTON, CANADA.

Heat Should be Inside

Not Outside

The value of a heat treating furnace rests in its ability to quickly develop and maintain an intense, uniform heat. But that heat must be *inside* and not outside.

BELLEVUE
FURNACES

are lined with heavy asbestos insulation in such a manner that external radiation of heat is reduced to a minimum. Bellevue Furnaces are simple and economical to operate. They are always under the accurate control of the operator. Built in seventy-nine different styles for every requirement of heat treating. Get our catalog now.

LA SALLE

Has an Advantage Over Other Grinders

There is some outstanding feature of all La Salle Grinding Machines that lends it exceptional productive ability.

The American Drill Grinder is especially adaptable for grinding twist, flat and three-lipped drills, because it has automatic lip rest and caliper jaw device, which assures proper clearance on all sizes of drills automatically. Send for descriptive matter covering our entire line of grinding machinery.

American Drill Grinder
For Wet or Dry Drill Grinding 1/8" to 2¼". Also 1/8" to 3½" dia.

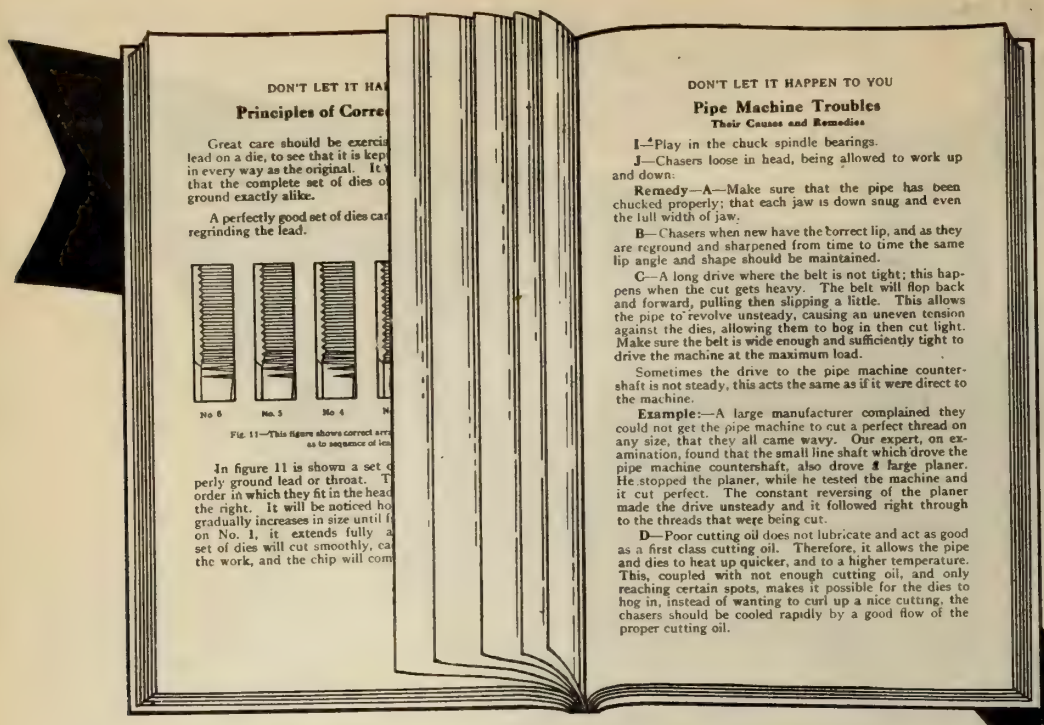
Jardine Universal Ratchet Drill

Time is expensive when a machine is standing idle, waiting for repairs.



On the average repair job, this machine completes the drilling in less than the time required to set an ordinary ratchet to begin.

Weight, 40 lbs. Price, $26.50 net.

Sold by all Machinery and Supply Houses.

A. B. JARDINE & CO., Limited

HESPELER, ONTARIO

The latest pipe machine hand book. 60 pages of valuable information. Close to 75 drawings and photographs. Send in the coupon today.

Questions and Answers to Pipe Machine Troubles

A valuable hand-book free for the asking-----

You'll find the answer to your pipe machine problem in the new Williams hand-book "Don't Let It Happen To You!" Whether it is how to grind dies, what kind of oil to use, or how to eliminate wavy, chattering threads, you'll find the practical answer in the new Williams 60 page hand-book entitled "Don't Let It Happen To You!"

The first chapter is an interesting illustrated short story that carries a smile and a moral for every pipe user. You will enjoy reading it.

A following section takes up the proper lip, clearance lead, chip space, etc., under the chapter heading "The Principles of Correct Pipe Threading."

Other chapters are devoted to "Care and Repair of Dies," "How to Properly Grind Dies," and perhaps most important, from the standpoint of practical value, "Pipe Machine Troubles—Their Causes and Remedies."

There are close to 75 drawings and photographs and the articles have been written by men of practical and long-time experience in the use of pipe machinery.

Clip the coupon. Mail it now for this book which is as valuable to a pipe machine user as a slide rule to an engineer.

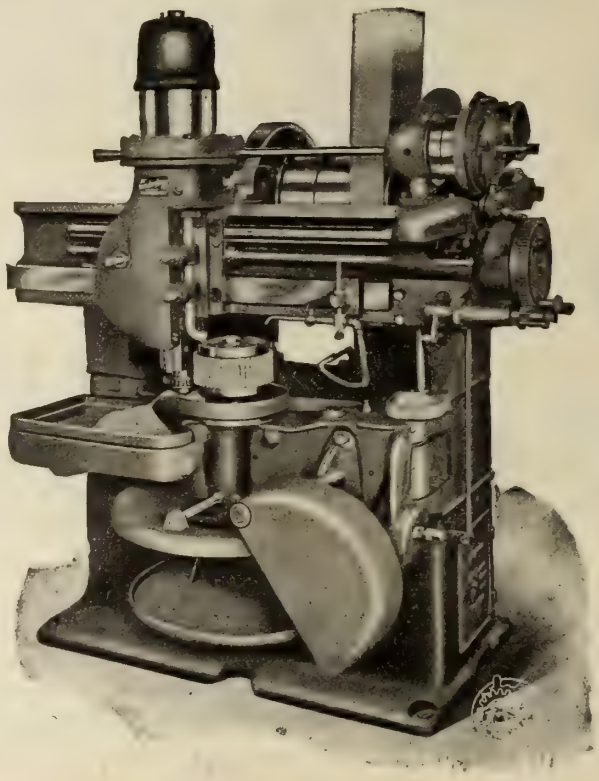
Gear Cutting With the "IFS" Left Out

The Gear Shaper Way



A production manufacturer knows that he will secure good gears IF he has an accurate cutter, an accurate machine and a machine working on the correct principle. The whole question of good gears is resolved in this little word "IF."

When the Gear Shaper was originally designed, the question of "IF" was taken into consideration and every possible means known to mechanical engineering was employed to eliminate the "IFS" from gear cutting.

That we have been successful in solving the problem is evidenced by the fact that each ensuing year sees a larger number of manufacturers adopting the Gear Shaper method.

How the Gear Shaper has accomplished this is clearly explained in our general catalog "Commercial Gear Cutting," which is a treatise on the subject of Gear Cutting with the "IFS" Left Out.

Send for your copy to-day

The Fellows Gear Shaper—the machine which has taken the "IFS" out of gear cutting

Made to Stand Hard Service

USERS of Butterfield Taps, Dies, Drills, Reamers and Milling Cutters notice that these tools can be pushed just a little harder than most other tools of their kind; they notice too, that Butterfield tools retain their cutting edge longer and require a minimum amount of regrinding. That's why Butterfield Tools are in demand, not only in Canada but throughout the world.

CANADIAN HART WHEELS

Vitrified -- Silicate -- Shellac

Canadian Hart Vitrified Wheels-recommended for the majority of grinding jobs. May be used wet or dry; give better all-around satisfaction and have a longer life.

Canadian Hart Silicate Wheels-- can be made in twenty-four hours and are often substituted when it is inconvenient to wait the required length of time for Vitrified Wheels.

Canadian Hart Shellac or Elastic Wheels---indispensable for slotting work where a thin wheel is required or for work requiring a special finish. Can be operated wet or dry.

Tell us what you want to grind and we will tell you the wheel to use for the best results.

"There is the Only Heater I Will Recommend"

The President was talking—
"There, gentlemen, is the only heater I will recommend for our new foundry extension! We have tried every possible imaginable system and each time we have had trouble of one sort or another. Last fall, though, I put in a Skinner Bros. (Baetz Patent) Heater and now—well, our heating troubles are past! We now have the same even temperature all day long, sand doesn't freeze, and the foundry is quickly reheated when monitor windows are closed after pouring."

Simple and Economical

The heater is portable—requires no special foundations—installation cost is 15 to 50 per cent. lower than any other type—operating cost is equally low. No outside pipes or ducts required—performance strictly guaranteed.
Find out more about this heater. If you wish, we will send you names of users so you can make your own investigation.

Mechanical Details
Steam-Coil Type

Built as an individual enclosed unit with a series of pipe coils compactly mounted above a powerful fan-wheel. Coils are heated by exhaust or live steam. Cold air is drawn into the heater by the fan, impelled upward and around the coils, and, after being heated, is diffused through outlet hoods to every part of the open area. No pipes or ducts used. The fan is operated by any power available.

Direct-Fired Type

Where steam is not available, we supply our direct-fired type DF, which burns coal, coke or wood. Built on the same scientific principle as type SC. The fan is operated by any power available.

Landis Pipe Threading Machine

The Walworth Manufacturing Company, New York, were interviewed regarding the performance of their Landis Pipe Threading Die Heads and Machines. Here are two of the questions and answers:

Q. How long do your chasers run without regrinding?
A. Those on the machine shown have not been touched for a year.

Q. How long does it take to cut a thread?
A. Three inch pipe thread, 20 seconds; twelve inch, 3 minutes.

The operator claims his Landis is the best pipe threading machine made and that a day's work on it does not tire him.

Profit by the experience of hundreds of firms using Landis Threading machines. Avoid trouble and be assured of good threads, high production and low cost of upkeep by installing a Landis in your plant **now.**

Write for catalogue and send us your specifications. We will be glad to show you why the Landis pays.

Giving Brand New Motor Advantages to an Old Block

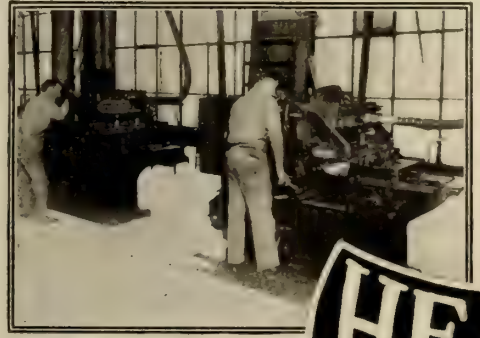
Can you see what that means to every motor owner under the present conditions? Hundreds are anxious to have their cylinders ground and fitted with new pistons and rings, but delay because it is necessary to send the block to some distant point or in some cases out of Canada.

If your regular business is dull, why not install a Heald Grinder and get some of the profits in this new field that are just waiting to be picked up?

This is especially true in the Fall when motorists are having their cars overhauled after a hard summer's run.

The possibilities are unlimited, for here is a virgin field in many localities, while in a few spots where they are in a position to handle this trade they are working three shifts.

Inquire from the neighboring garages and your friends how much work they can give you. Investigate thoroughly and then remember that 90 per cent. of the manufacturers of automobiles use Heald machines exclusively for grinding.



No other machine or method of finishing will give the quality, production or profit. Let us get together on the subject. It will be to our mutual advantage. Write, wire or phone.

The Heald Machine Co.

51 New Bond Street
Worcester, Mass.

IN THE PACKARD SERVICE SHOP

Since September of last year 1,820 car and truck cylinders have been reground on the Heald Machines in this shop.

ABOUT THE HEALD MACHINE

Simple — self-contained — moderate price—easy to set up—does not need a skilled mechanic to operate it, yet grinds accurately within one half a thousandth of an inch.

Franklin Die-Castings Used in Electrical Appliances

A Help in Electrical Progress

In modern electrical progress, as in many other fields of industry, manufacturers quickly took advantage of the economy and speedier production possible with the die-casting process. Franklin Die-Castings are used by many of the best known manufacturers of telephones, telegraph instruments, electric fans, drills, cloth cutting machines and various other electrical devices.

In 1892 we originated the Die-Casting Process. For nearly thirty years we have been reducing the cost and simplifying the output in many fields of industry. The addition of a special process for the production of finished brass castings enables us now to offer parts in brass, bronze, aluminum, tin, lead, or zinc base alloys as conditions require, thus meeting a still wider range of work.

We quote from samples or blueprints

Where Do You Use Grinding Wheels?

Norton **Alundum** *and* **Crystolon** grinding wheels are used today for thousands of jobs where other methods were formerly considered best.

With our several artificial abrasives to select from, each especially fitted for certain kinds of grinding, plus a long range of grit sizes and grades, chosen by us to give best service for each operation, manufacturers find that "grinding" is quicker, cheaper and generally more satisfactory for their work.

From our many years of experience we are familiar with these developments and are in a position to tell you whether or not grinding would be more practical and more economical for work like yours than your present practise would be.

Let us offer suggestions in your case. Explain your work to us; let us give you the benefit of our experience.

Perhaps Norton Alundum wheels, Norton Crystolon wheels or Norton Alundum polishing grain can reduce your manufacturing costs.

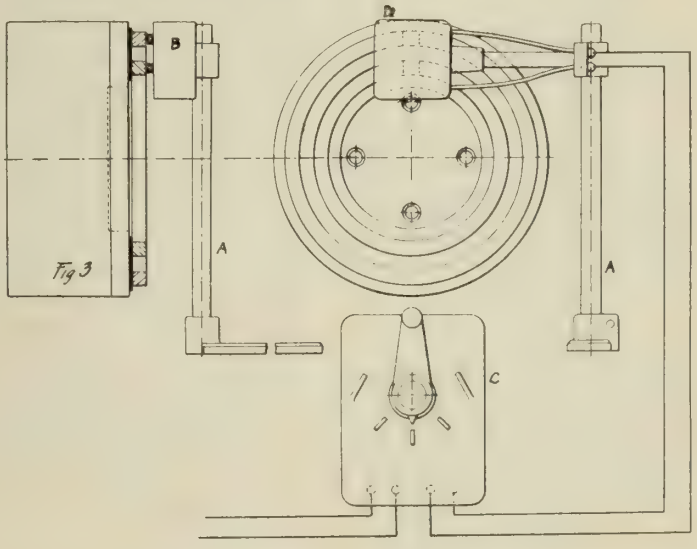
VOL. XXVI. No. 9 September 1 1921.

Magnetic Chucks Require Careful Mounting

Mounting Can Be of a Permanent or Temporary Character—Magnetic Holding Faces of Chuck Must Be Absolutely Correct

By F. HORNER.



THESE somewhat delicate pieces of apparatus call for special treatment in regard to their mounting, whether it is of permanent or of temporary character. The permanent attachments comprise those of rotary work in lathes and grinders, where a face plate or adapter is employed. What may be classed as temporary mountings are those on the tables of planers, millers and grinders, where removal is necessary at intervals. In either case careful care is essential to obtain truth of the magnetic holding faces, both in the original setting, and in subsequent replacements. The absolute prevention of bruises, burrs, and any deformation by careful peening is imperative; so also is the cleaning off of dirt, grit and cuttings from the attaching surfaces of the work, or chuck or table as the case may be.

If any of these matters are neglected the work that is machined will not be parallel, and the attempt to work to fine limits will be defeated. On the grinding machine it is always possible to skim over the magnetic chuck and face up, but this should only be done at comparatively rare intervals, otherwise the metal of the face will soon become thinned and weakened.

A particular feature of magnetic chucks is the necessity for conveying the current without danger of interruption, and of making sure that access of water, oil, or dust and cuttings shall not cause failure, or short circuits, which would act disastrously during the progress of some operations. The importance of guarding against a breakdown applies both to the chuck body and joints, and to the leading-in connections, or running contacts as the case may be. The greatest risks of course occur when the chuck is used freely during tooling, the latter instance being that of submerged chucks, which are flooded entirely for grinding certain articles.

With regard to the preliminary question of attaching chucks, either by means of base plates, or direct to the table faces, the important point to observe is that no sharp corners are left on the meeting places to become burred up, and that the pulling together takes place equably without irregular strain caused by tight-fitting bolts. A fruitful source of straining is the fact that the holes are not drilled or tapped square, and the bolt or screw pulls to one side instead of proceeding straight in. The familiar practice of relieving the fit of sharp corners by chamfering the one, and grooving out the other, should always be adopted, to ensure that the fit shall be perfect on the flat faces. A further precaution lies in countersinking the screw holes before tapping, the removal of the metal at the mouth preventing the swelling up and around the hole. The screws must be a slack fit in their clearing holes, and the drilling needs to be fairly accurate in order that no screws shall bind sideways in opposition to others. The same remarks refer to the mounting of chucks on large running plates or gear rings, as in the heavier surface grinding machines.

When a chuck is merely bolted as required to the table of a planing, milling, or grinding machine, this has to be carefully inspected for burrs, and if

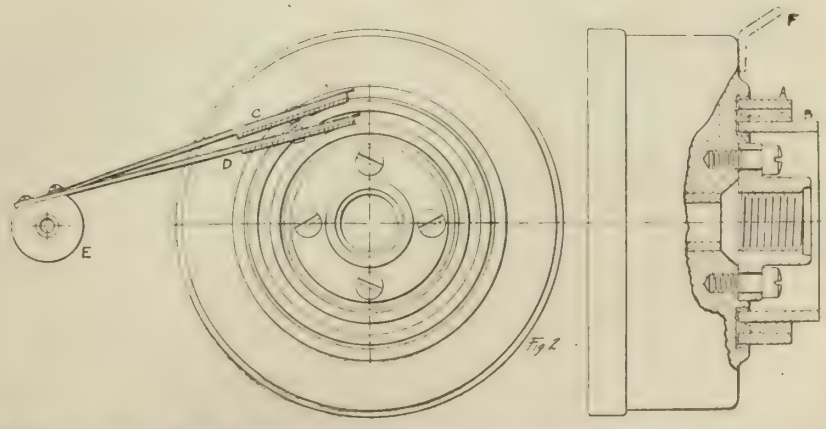


Fig. 3—Upper View. Brush gear and connections for face contact rings.
Fig. 2.—Lower View. Mounting and brush gear arrangement.

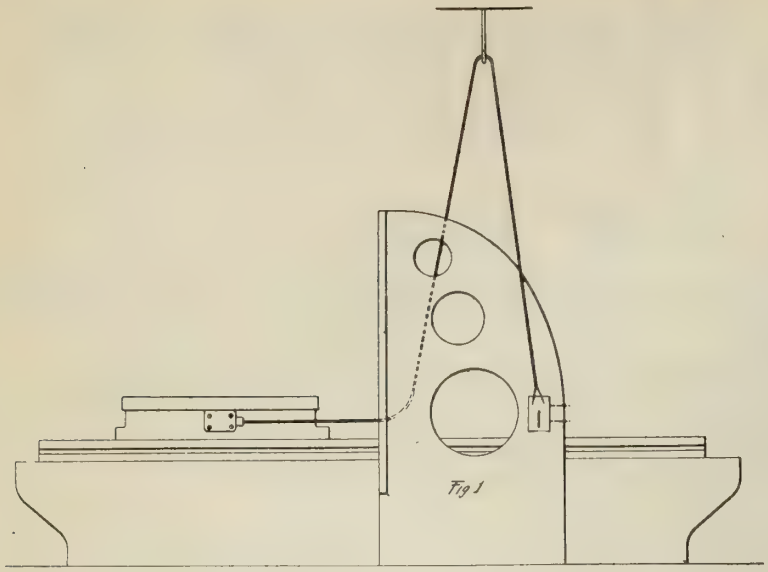

Fig. 1.—Method of suspending cable for planer chuck.

necessary touched off. The table must also be true in regard to the plane of movement. Without this accuracy, parallelism in the output is impossible, and in the case of swivelling or of tilting chucks, the angles ground will not be true as read off the graduations.

Conveyance of Current

The conveyance of current is variously effected, according to whether the chuck moves or not, and whether the movement is of a reciprocating or a rotary character. If there is no movement, as in some kinds of grinding machines, and in shaping machines, it is only necessary to bring a flexible cable in any convenient way to the chuck. But when there happens to be a reciprocation of more or less magnitude, the cable must be disposed to allow perfect freedom without possibility of interference with any moving part of the mechanism, or obstruction to the operator. A short reciprocation may be accompanied by slinging the cable from a stick clamped in a convenient manner on the top of the planer housings, allowing enough swing to and fro; or the current can be brought down from the ceiling or from a beam to the table end, a switch and flexible cable making connection to the chuck. When there is a considerable length of stroke the best plan is to provide a long cable, carry it up from the switch on the flank of a housing, and over an eye attached to a beam, as shown at Fig. 1. Protection against chafing is, if necessary, afforded by rubber covering on the lower portions.

When a chuck revolves, a rubbing contact becomes necessary to transfer the current, and there are several methods of arranging the details, some of open or unprotected type, some semi-protected, and others completely enclosed. Construction varies sometimes according to whether the chuck is on a horizontal or a vertical face, which has the result of modifying the spindle arrangements. Practice is also divided between making contact on peripheries or against faces, examples of both being shown. In Fig. 2 is shown the back of an O. S. Walker chuck, the contact rings "A, B," being bedded into the back face; while the strips carrying the brushes, "C and D," are mounted on a block "E," located conveniently at the rear. The switch is either placed close to "E" or is brought to the front of the machine for convenience. The block "E" requires to be kept clean, otherwise there will be a short-circuit. A partial protection against water is to screw a rim on the chuck, as indicated by the dotted line in Fig. 2, at "F." This, however, can be more easily done when the contact rings are of the face type, in which instance the rim does not come so near in the way of the brush strips. A specimen of mounting with face rings on a chuck made by Messrs. Humphreys & Sons, Oldham, England) is given in Fig. 3.

In this case a column "A" is utilized to clamp in any suitable spot, and receiving the carbon holder "B," the wiring is carried out by the lines, with connections to the demagnetizing switch "C."

The most effective device for guarding against breakdowns through access of grit or water or oil to the contacts is to transfer them to the tail end of the spindle, and convey a flexible lead through the hole in the spindle to a plug socket which is entirely covered in. The lay-out of a fitment by Messrs. Humphreys is illustrated in Fig. 4, which shows the plug socket at the front and the connecting cable going through the spindle and thence to the terminals "A,A." The latter are screwed into a drum carrying the two contact rings, "B,B," on which the carbon contacts "C,C," rub. The wires are brought through the open end of the guarding ring, "D," retained from movement by a peg resting against a part of the machine, and screwed into the hole shown in the section.

The fitting of the drum into the spindle end is effected by means of a pin shank as shown, with hexagon heads for loosening purposes. Ball races located at "E,E," allow of long-continued rotation with the minimum of friction and no trouble through heating. A simple design of gear is used on occasions where there is no need to afford the complete protection, the casing "I" being omitted.

Guarding the Contacts

The problem of guarding the con-

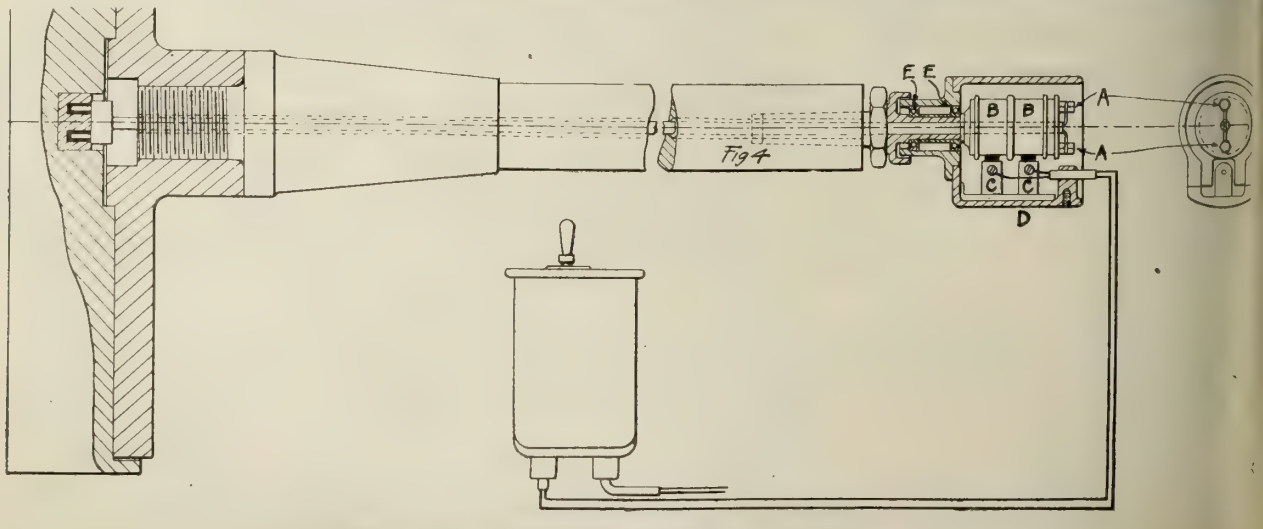

Fig. 4.—One method of guarding against breakdowns.

in he case of vertical-spindle grinding mines is complicated by the action of gr ity on the water that floods the ch k surface. Special deflecting or trping devices are incorporated to nto the water from reaching the underside of the chuck and the contact rings, wh dust and grit are also excluded, a recision which is equally essential for the safety of the bearing, and the annul race when such is used.

I the O. S. Walker rotary surface r er the protective arrangements oc- ins represented by Fig. 5. A deep gh "A" goes round the chuck rim and e vater which falls down this cannot wards to the contact rings because e presence of a deep annular rib ising up above the bottom of "A." ir ventilation of the chuck goes on picted by the arrows.

L ge chucks require special lubricat- g rovisions for the annular race, and is act can be adapted to secure im- ty from access of moisture or dust aking an oil-bath. The Blanchard ne offers a case of this sort as at Fig. 6; the oil bath, marked completely guarding the rings. The flange around the rim of the bl arrests the water or dust and deflect it into the annular groove of the sliding table lip, in which drain holes communicating with the catching tanks are made.

A istake which some toolmakers, or of magnetic chucks make, is that drilling in holes for the purpose of locating attachments of fixtures or stops. This practice is reprehensible because it runs the risk of producing a breakdown through access of water or oil, and serious injury may be caused to the parts. Some parts of the face or edge can be safely drilled into and tapped, but without an accurate knowledge of the thickness it is not safe to do anything in this way. A better method to adopt when one wishes to have extra stop or location devices, is to provide these outside the chuck, or in other words to arrange them off the machine altogether from an angle-plate or other fixtures, thus leaving the chuck unimpaired.

Another detail of the mounting ar-

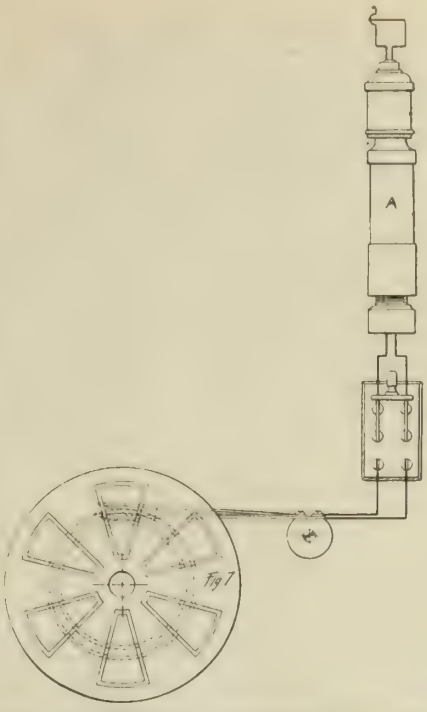

Fig. 7.—Wiring arrangements of chuck with resistance interposed.

rangement requires to be mentioned, beyond the necessary fuse which is placed in the circuit to prevent the burning out of the coils. This detail is the provision made for modifications in voltage. In cost cases chucks are wound for certain voltages, usually either 110 or 200. But a 110 volt chuck may be used on a 220 volt circuit by interposing a suitable resistance unit, as in the diagram of a Walker chuck given in Fig. 7, where "A" is the resistance. In the Heald chucks there is a special construction of the terminal or volt box, which has connections that may be changed by joining up the lead wires in different ways. This obviates the necessity for a resistance in the circuit.

IMPROVING LIFE BOAT SERVICE

Excellent results have been obtained by the British life boat service in the use of tractors in place of horses to launch the boats, but this is only one of several recent improvements. Many experiments have been made recently with mechanical devices for effecting communication between the life boat and the ship in distress. These experiments have lead to the adoption of a special line-throwing gun invented and made by a leading firm. The gun is able to throw a half inch line from 60 to 80 yards in all conditions of weather. The line is coiled in a tin cylinder which fits over the barrel and the end is fixed to a hollow steel projectile fired from the gun with a cordite cartridge. The whole contrivance is so light that it is not much heavier that a service rifle and can be fired from the shoulder with only a slight recoil. It is expected that this innovation will lead to the saving of many lives under circumstances when the lifeboat cannot approach the ship closely enough for a line to be thrown.

A British engineer has recently devised a small pump which consists of a piece of rubber tubing bent into a loop, with a wooden frame outside the loop and a circular cam inside. By placing the cam out of centre and revolving it the rubber tube is squeezed in a rotary direction giving a kind of "milking" action which will force liquid through it. One end of the tube then becomes the suction pipe and the other the delivery pipe of a very neat and efficient form of pump. The inventor after having made a pump out of a serviette ring and piece of rubber tubing, has taken out a patent for a regular engineering mechanism on the same principle. He proposes to use a flexible rubber or leather band suitably water-sealed on its width, in place of the tubing, and cast iron or gun metal casing with suction and delivery branches. This type of pump, has no valve and will therefore be suited for use in cases where pump valves are apt to give trouble.

The new line of electric furnaces which has recently been added to the products of the Westinghouse Electric & Mfg. Company is described and illustrated in catalog 9-C, which is being distributed. This type of furnace includes heats of 1,800 to 2,000 degrees F

Selection and Proper Use of Cutting Tools

The Practical Side of the Subject of Cutting Tools—Their Selection—Use—Manufacture—Storage and Maintenance—Standard Tools and Their Design

THE SUBJECT of cutting tools has been dealt with theoretically and analytically in the article in July 21 issue. It is proposed to continue by considering the practical side of the question. If the previous article has served its purpose, it has shown those who are intimately concerned with the use of tools that tradition must go by the board—that efficiency in the machine shop largely depends on the character of the tools used—that the tool question is bigger than most people imagine, and that it will pay to sift the subject to its fundamentals, each shop deciding on a standard tool scheme to suit its own conditions and insisting on its being carried out.

It is impossible to go fully into the practical side of tool using—the subject is so vast and so varied; there are so many different conditions to be met. The shop where sewing machines are manufactured will need a widely different treatment to the shop where naval guns or armour plates are made. The principles underlying the tool question in these two shops, however, are essentially the same; the tool of ⅜-inch square section used in the one for taking minute cuts up to 1/16-inch in depth differs only in degree from the 3-inch by 2-inch tool used in the other. In this article it is only possible to consider the question as it presents itself to the average shop, where the tools used range from, say, ⅜-inch square cutters for turret lathe box tools to 1-inch by 1½-inch planer tools.

Assuming some such conditions, then, what scheme can be devised to ensure an adequate supply of efficient cutting tools that can be made at low cost and easily maintained in good condition?

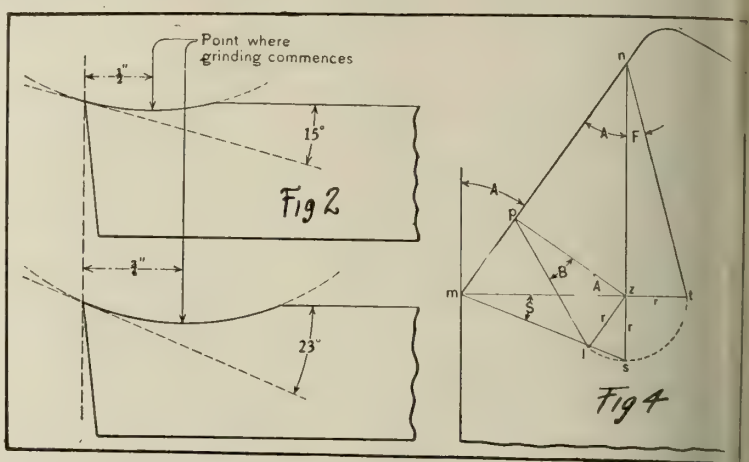

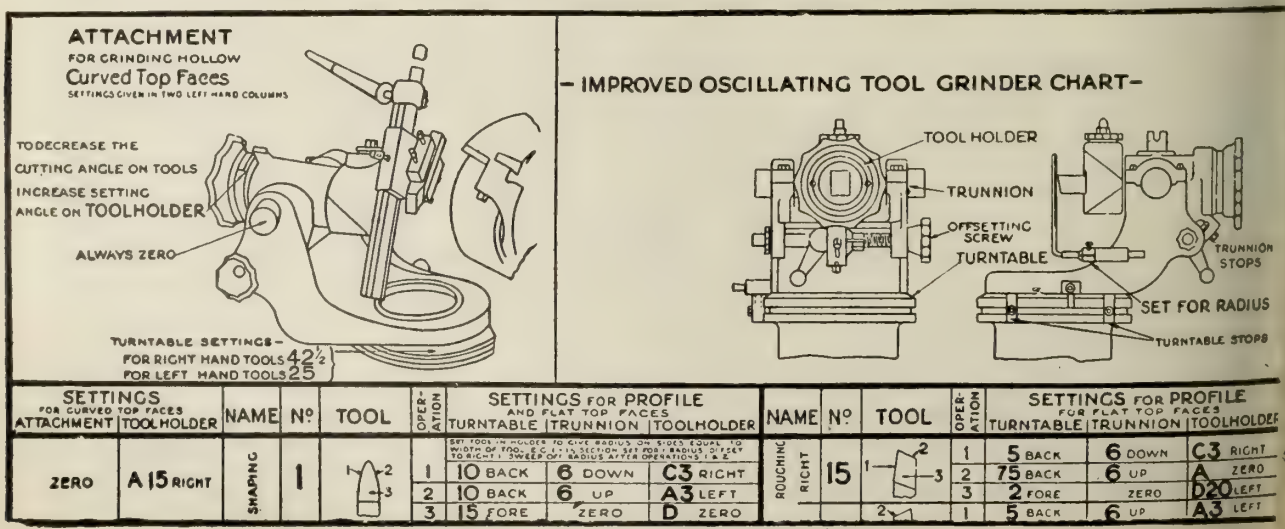

Fig. 2. Effect of commencing the grinding of a curved top face at diff nt distances from the cutting edge.
Fig. 4.—Showing style of gauge used.

An adequate supply means that no machine need ever be kept standing for want of a cutting tool any longer than is necessary to obtain a fresh tool from the stores.

Efficient cutting tools mean that for every operation on every machine there is a tool available that will give the desired result with the least expenditure of power, in the shortest possible time, and with the maximum of durability. Made at low cost and easily maintained means that the adopted system of tool making must be itself efficient.

In the Lumsden method of tool making the system of grinding is followed out by means of a chart shown in Fig. 1. This chart is based on the results of countless experiments and a wide experience gained in shops of all kinds. Of course it is not expected that the twenty five tools shown on the chart will cover every requirement, but it has been proved that it serves very well as the basis of a set of standard tools for any s p. Later on we will deal with each o separately, giving reasons for its x- istence, work for which it is suited n so on. Before touching on that pha o the subject, we will consider brie few points in the design of the grin machine used and its method of o a tion.

Briefly, the machine provides a m by which the entire nose of any sh e tool can be presented with ease t h flat face of an oscillating cup w It is absolutely necessary for eithe tool being ground or the wheel on v it is ground to be reciprocated a the face of the other; if not, the will rapidly glaze and refuse to cu this case the reciprocatory moveme done by power instead of muscula fort. All the adjustments of the too the wheel are easily made fron working position, and the operato

t all times see what is happening with-
it stopping for inspection.

For all tools with flat faces no at-
chment, template or former is requir-
l, all the adjustments necessary being
tained in the universal tool holder. For
ose tools that have hollow curved top
es a simple attachment is used. This
secured in the tool holder of the mach-
, while the tool is reciprocated across
e corner of the grinding wheel, the
mbination of angular positions of tool
d holder giving any desired amount of
rvature.

The Toolholder

The tool to be shaped is gripped in a
iple chuck, which can be rotated
ough a complete circle on its own ax-
The barrel which contains the chuck
carried in two trunnion bearings, so
t the tool can be swung through an
of about 10 degrees up or down. The
unions have endwise adjustments in
ir bearings for use when grinding
ius tools in which the centre of the
ius does not coincide with the centre
the spindle. The whole tool holder can
ate on a vertical axis, enabling any
or the end of the tool to be present-
to the wheel at any pre-determined
le. An inspection of the line drawing
the tool holder in Figure 1 will reveal
unlimited application of these move-
nts.

The Tool Chart

is desirable that the instructions
gin in any tool grinding chart should
ot only intelligible but also incap-
ab of wrong construction by the most
perienced operator. For this reason
hart gives the settings of the tool
re there are no alternatives, so that
chart is followed the correct ang-
e given to the tool. In other words,
hart tells the operator what to do,
n from his point of view is what he
wants to know.

actual angles reproduced on the
are those given in the chart. The

tool.

naming of tool angles, such as a
angle, side slope, front slope,
ee, and so on, is liable to misin-
ation, and has been abolished in
art. Instead, each tool is sketched
tool faces numbered to corres-
with the sequence of the grinding
ons. Thus confusion is entirely
ited, and the chart can be easily
easily understood, and easily in-
ed on the machine.

Th are three angular adjustments
th oscillator, each graduated in de-
es These are designated as the turn-
ble he trunnion and the tool holder
espe ively. The positions of all three are
separ ely specified for each tool face
to be round. The turntable graduations
read many degrees "back" or "fore"
from the zero position. The trunnion graduations read so many degrees "up" or "down," thus indicating the actual movement of the tool nose from the horizontal. The tool holder has four arrow marks labelled respectively "A," "B," and "D." The barrel in which it rotates is graduated so many degrees "left" or "right" of the zero. The four marks A, B, C, and D correspond to the four sides of the tool; when arrow mark A is covered by the graduations the top face of the tool is uppermost provided the base is flat on the base of the tool chuck. The marks B and D then correspond to the two side flanks while mark C corresponds to the base, on which no grinding is done.

Curved Top Faces

The advantages of the hollow curved top face have been set out in the previous article. A curved top face can be ground by this oscillator almost as easily as a flat face. The profile of the tool, that is the shape from the top, is first ground without the use of the attachment. When a batch of similar tools has been thus "profiled," the tools can be finished with curved top faces by means of the curved face attachment furnished with each machine in very little more time than would be required if they were ground with flat faces.

The degree of curvature given to the tool, and consequently the rake at the cutting edge, can be varied by commencing the grinding nearer to or farther from the cutting edge. This will be readily comprehended by referring to Fig. 2. This method of increasing the keenness of the cutting edge, however, may not be desirable owing to the resulting length of the ground face from the tool nose. Another method is open in such a case, and that is swiveling the attachment slide more towards a vertical position, a method which causes the tool to be reciprocated more on the corner of the wheel.

When using the attachment the trunnion setting must be at zero, that is, the barrel in which the attachment is gripped must be horizontal. For right-hand tools the position of the turn-table has been found by experiment to give the best results when set at 42½ degrees back, so that the front and the side of

Fig. 3.—Chart showing variations of tool No. 4 with the settings necessary to give each shape and the class of work for which each is suited.

the wheel make equal angles with the tool. When grinding left-hand tools, owing to the position of the tool nose relative to the movements of the wheel, the turntable should be set at 25 degrees back. These two settings need never be altered for any shape of tool.

The tool is secured in the holder of the attachment in such a position that the cutting edge is parallel with the slide. A tool having a curved cutting edge is set so that a tangent with the average centre of the cutting edge is similarly parellel to the slide. The slide is set to 15 or 20 degrees (see chart, Fig.1) from the vertical, and clamped in that position. Grinding takes place without the oscillating motion of the wheel.

The wheel in then advanced and adjusted sideways until it just touches the tool at a point distant from the cutting edge an amount varying with the size of the tool and the degree of curvature required. This amount is decided by the position where the deepest part of the grinding will ultimately be. For a small tool, say ¾-inch by ½-inch, it can be about ⅜-inch; for a large tool, say 3-inch by 2-inch, about 2-inch will be necessary. A good rule to follow is to make the length of the top face equal to the width of the tool. In any case it will soon be seen as grinding proceeds whether the desired effect is obtained or not, and correction made accordingly.

The tool is then passed up and down across the corner of the wheel by means of a lever at the top of the slide. While grinding proceeds the wheel should be fed alternately forwards and sideways by means of the two hand wheels which control these movements. Grinding continues until the cutting edge is reached. It should always be the endeavor of the man in charge to have tools ground in batches; this decreases the cost of making the various settings, and encourages greater efficiency in the operator.

The swiveling movement of the turntable on its vertical axis is extremely handy for grinding radius and round-nosed tools. To do this the tool is set so the centre of the desired radius is exactly over the axis of the turntable; then with the wheel stationary or oscillating but slightly the turntable is rotated back and forth until the desired curve merges into the sides and end of the tool. To facilitate setting, a radius gauge is provided. The procedure is as follows: First grind the end of the tool with the necessary clearance, then the side of the tool, also with clearance. Run the wheel back and reset the tool in the chuck, using the radius gauge to determine the forward position of the tool nose.

Next adjust the barrel of the chuck sideways in the trunnion bearings, using the graduated scale to bring the centre of the desired radius over the axis of the turntable. Set the turntable to 90 degrees back, bring the wheel up till it just touches the tool, and set the stop which limits the forward movement of the wheel. Run the wheel back again, then commence grinding, swiveling the turntable and feeding the wheel forwards till the stop is reached, when in will be found that the radius is completed.

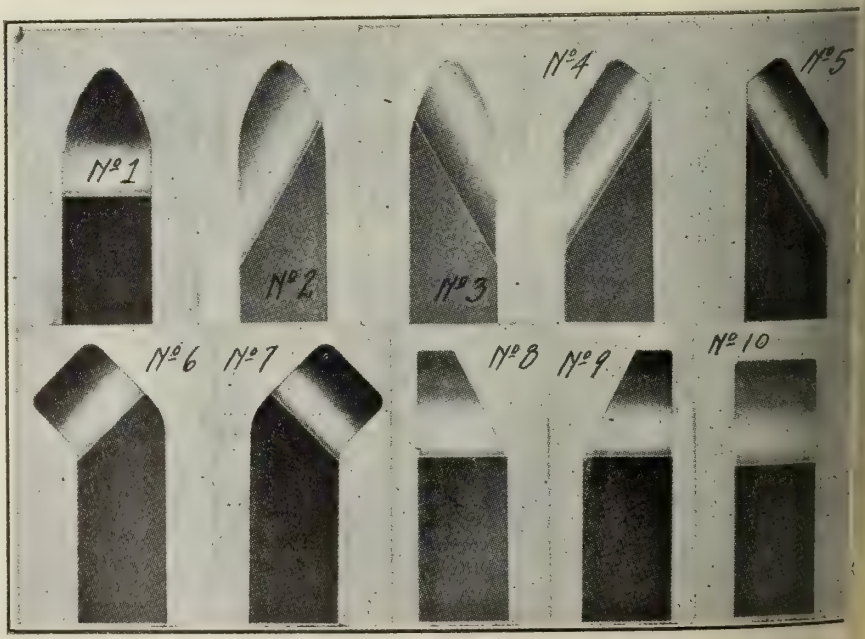
Standard Tools

In deciding on the set of tools incorporated on the chart, the authors have had in mind the elimination of forging as far as possible. Sixteen out of the twenty-five tools shown can be roughed to shape from a piece of straight bar. Four of the remaining nine need only bending, a very simple operation. The two tools for finishing fillets, Nos. 24 and 25, need only forging when the radii are larger than, say, half the tool width. The twenty-five tools shown cover the majority of the requirements of the average shop, as will be seen later when their purposes are described.

Tools numbered 1 to 14 can be ground with a hollow curved top face, and it is strongly recommended that they should be so ground, for the reasons previously advanced. The requisite settings for grinding these tools to such a shape that they will be suitable for machining mild and the lower carbon steels are given on the left of the chart. These settings replace those otherwise used for grinding the top face flat, and do not affect the shaping of the top profile.

All the other settings given have been chosen, as the result of a very wide experience, to give a tool suitable for 30-ton steel, with the exception of the last four, which are intended for special purposes. The resulting rake of the top face, can, of course, be varied to suit the material to be machined, the keenness being increased for softer materials and decreased for harder materials.

The No. 1 is a round-nosed tool intended mainly for planing and shaping. The top face slopes away from the point, there being no side cutting angle at all; it also has clearance on both sides of the tool, so that it can be used for feeding in either direction. It is in addition useful tool for necking the journals axles and shafts. The roundness of th nose can be varied to suit different co ditions. For instance, for turning a sle der camshaft between the cams th point should be made fairly slende say ⅛-inch radius, whereas when tur ing railway carriage axles, where cha ter is not likely to occur, the nose c be much blunter, say ¼-inch up to ½ inch radius, depending on size of to This tool is preferably made from ste of a depth about one and a half tim its width.



Grinding Instructions

Set the end of the tool blank by mea of the radius gauge to give a radi equal to the width of the tool sectio

Adjust the trunnion to the right amount also equal to the width of t tool.

The two sides of the tool should ground complete in two distinct op ations. In grinding face 1 the toolhol is rotated till the base of the tool is permost. Set the turntable to 10 degr "back," and grind the side of the t away for a length equal to the t width; then, without altering any justment and while the tool is still contact with the wheel, unclamp turntable and slowly sweep it round the left till the tool leaves the wh Repeat this operation on face 2 wi out removing the tool from the toolh der; this time, however, the base of tool will be downwards.

Note particularly that to obtain correct clearance on the two sides trunnion is set to 6 degrees "down" the toolholder to C.3 degrees "rig for face 1. Both these settings are versed for face 2, that is, the trunnio set to 6 degrees "up" and the toolhol to A.3 degrees "left." The point sho be just touched up, giving 6 degrees clearance, the settings being (tho this is not given in the chart):—

Photographs of tools from No. 1 to No. 10.

Turntable.	Trunion.	Toolholder.
90 back.	6 up.	A zero

The point can be rounded off later by and on a plain grinder, although on rge tools, which require a large radius the point, it can be done in the os-llating grinder by setting for the de-red radius. The top face is then ground give the desired rake—in the chart is is given as 15 degrees, as any great-keenness would cut too deep into the ol. It is, therefore, strongly recom-ended that this tool be always ground th a hollow curved top face, as a keen-rake is obtained without weakening tool.

For hard materials such as cast iron, flat top face with 10 degrees rake is ter, the settings for Operation 3 be-

rntable.	Trunnion.	Toolholder.
0 Fore.	6 up.	A zero.

Tools Nos. 2 and 3 have a similar pro-to tool No. 1, the difference lying in the rake of the top face. This has as well as front cutting angle, so tools can only be used for feeding one direction. These are general pur-e tools for right and left-hand rough ning, though they are preferable to 1 for shaping and planing steel n the feed of the tool is in one di-ion only.

e tools are shown in the chart with sides rounded, this being the form t suitable for ordinary purposes. re they are used for heavy roughing reference to tools Nos. 4 and 5 (this, ever, is not recommended) the round-of the non-cutting side can be left the end of the tool being ground off degrees "back" and 6 degrees clear-, No. 2 tool being ground with the face upwards and No. 3 with the top downwards. This agrees with the in that for heavy cutting as much as possible should be left on the nose to absorb the heat, but will on-ply to tools of larger section than, ¾-inch by 1-inch.

erally speaking, these tools should ade of steel with a depth about nd a half times its width, though me small American lathes it will und necessary to employ a section to one. Grinding instructions as ol No. 1 will apply, with the ex-n of grinding the top face.

n grinding these tools with a hol-rved top face, they should be set attachment at an angle of 30 de-with the slide, as this setting the curvature run away from the g edge in a manner suitable for dinary purposes. On small tools, based only for light cuts, this angle decreased with advantage to 20 even 15 degrees. When the non-cutting not rounded the settings to be stead of those given in the chart

Tool o.

	Turn-table,	Trun-nion,	Tool-holder.
2, 4. 2.	80 back	6 up.	A zero
3, 5. 1.	80 back.	6 down.	C. zero.

Tools Nos. 4 and 5 are those strongly recommended for nearly all rough turning and planing because they adapt themselves so readily to the most efficient form for cutting all kinds of materials. On the standard tool chart the forms of tools given are those suited for general work, but full instructions will be given for arriving at the form most suitable for definite individual conditions.

The cutting edge, numbered 1 in the diagram, can be ground to any angle from 5 to 55 degrees and can be made of any length, according to the depth of cut.

The variations to which these tools are subject are given in the diagram and chart, Fig. 3, with the kind of work for which each is suited.

The cutting edge, whatever the form and rake of the tool, must be approximately horizontal, and in Fig. 3 the angles specified ensure this. For those who are interested in knowing the means whereby the various settings for the rake angles suited to different materials are ascertained, the following formulae and its explanation may be cited.

Refer to figure 4, which shows a tool with the cutting edge at A degrees to the side of the tool. The line pz drawn in a horizontal plane at right angles to the cutting edge gives the rake of the top face as B degrees, shown in triangle zpl. Then a vertical line from horizontal line pz to the top face is zl. The horizontal lines zm and zn are drawn perpendicular to and parallel with the side of the tool. Then the angles which these two lines make with the top face are respectively the side and the front cutting angles which can be set on this machine by means of the toolholder and turntable adjustments.

The lines zlzs and zt are all equal as represent the vertical line from point z to the tool face. Call them r, then:

$$\frac{r}{pz} = Tan\ B.$$

$$r = pz\ Tan\ B \quad \ldots(1)$$

$$\frac{pz}{mz} = Cos\ A \quad \ldots\ldots\ldots(2)$$

$$\frac{pz}{nz} = Sin\ A \quad \ldots\ldots\ldots(3)$$

$$Tan\ S = \frac{r}{mz}$$

$$\text{Substituting (1)} \quad = \frac{pz}{mz}\ Tan\ B.$$

$$\text{Substituting (2)} \quad = Cos\ A\ Tan\ B.$$

$$Tan\ F = \frac{r}{nz}$$

$$\text{Substituting (1)} \quad = \frac{pz}{nz}\ Tan\ B.$$

$$\text{Substituting (2)} \quad = Sin\ A\ Tan\ B.$$

Thus angle F, the front cutting angle, is also determined in terms A and B.

The same problem can be solved graphically by drawing the diagram (Fig. 4) to the correct angles, then measuring angles S and F with a protractor to the nearest degree. Nos. 4 and 5 tools should have shanks of sections with a depth one and a half times the width.

Grinding Instructions

The tool blank needs no special setting in the holder beyond the elementary one of placing the base of the blank flat on the bottom of the holder.

Grind side angle 1 to the requisite inclination of the cutting edge, then turn the tool over and grind front angle 2. In a small tool or one to be used for light cuts only, make face 1 quite short and grind face 2 till it almost joins it. When grinding a curved top face, the cutting edge, whatever its inclination, must be set parallel to the attachment slide.

The setting of the machine toolholder is given as A.20 right or left—this is correct for most tools. Very small tools can be ground with the slide set nearer the vertical, while for very large tools the angle can be increased to, say, A. 30, beyond which it is not desirable to go. The point of the tool can be radiused by hand, though, if desired on large tools, it can be rounded on the machine, with 6 degrees clearance, setting to the desired radius by means of the radius gauge and carefully noting the position of the centre of the tool width, in order to offset the tool correctly. One point that should be rigorously watched in making these tools is that the cutting edge must be long enough for any depth of cut it may be called upon to take, while at the same time it should not be made any longer than is necessary.

These Tools Nos. 6 and 7

These tools are precisely the same in principle as Nos. 4 and 5. They are bent for the purpose of reaching outside the tool rest in those cases where the saddle cannot be brought close enough to the work to employ a straight tool. The blank should be bent to an angle of 45 degrees. As the use of bent roughing tools is limited to special and but few cases, it is not necessary to consider variations in its angles, as the expense of providing tools with the possible variations would not be justified. Generally speaking, any variation desirable can be obtained by inclining the tool in the tool rest. A section of 1 to 1½ will be found generally suitable for this tool.

Grinding Instructions

These will be generally as specified for tools Nos. 4 and 5. The rake of the cutting edge can be varied to suit different materials, the angles given for the top tool but one in Fig. 3 being all the variations necessary.

Tools Nos. 8 and 9 are intended for fine finishing cuts on lathes, planers or shapers. Sides 1 and 2 are ground with clearance, so the corner between them should always be the leading corner. These narrow finishing tools will rarely if ever be used in the larger sections; on the other hand, the broad

finishing tool, No. 10, will rarely be used in the smaller sections. Theoretically, the width of the cutting edge should be about twice the intended feed, but as this cannot be readily determined, it will prove a good rule to make the cutting edge half as wide as the tool shank. These tools will give the greatest satisfaction if made of a section having a depth twice the width.

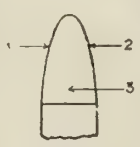
Grinding Instructions

First grind the end of the tool, this being the cutting edge, giving it 6 degrees of clearance. The front edge of the tool can next be thinned down to half the width of the shank by grinding off at 25 or 30 degrees with the side.

For cutting steel, it is strongly recommended that these tools be ground with hollow curved top faces, the tool being set in the attachment at right angles to the slide, top face turned towards the wheel. The toolholder setting of A. 15 right will give the right amount of curvature for all tools up to ¾-inch by 1½-inch. Larger tools can be ground at a toolholder setting of A.20 right. For cutting cast iron a flat top face with 10 degrees rake is best; this is obtained with settings for operation 4 of

Turntable.	Trunnion.	Toolholder.
10 Fore.	Zero.	D zero

Tool No. 10 is a broad finishing tool, and will generally be made of square section steel, 1½-inch by 1½-inch a larger.



This tool will be generally more us for planing than for shaping or turnin Grinding operations are generally sir lar to those given for tools Nos. 8 and Sides 2 and 3 are, however, both grou with clearance, so that the tool can fed in either direction. For cutting st it should be ground with a hollow cur top face. For cutting cast iron, it sho have a flat top face with 10 degrees rake, the settings for operation 4 be

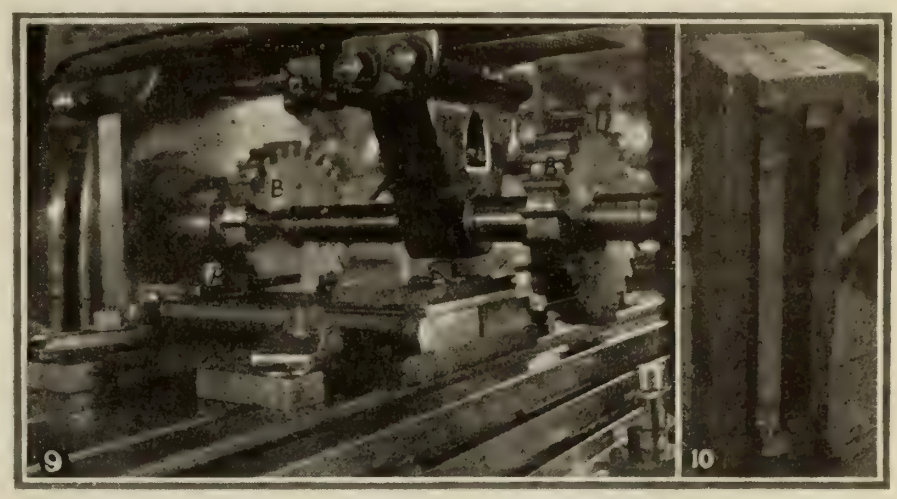
Making Connecting Rods for Marine Engines

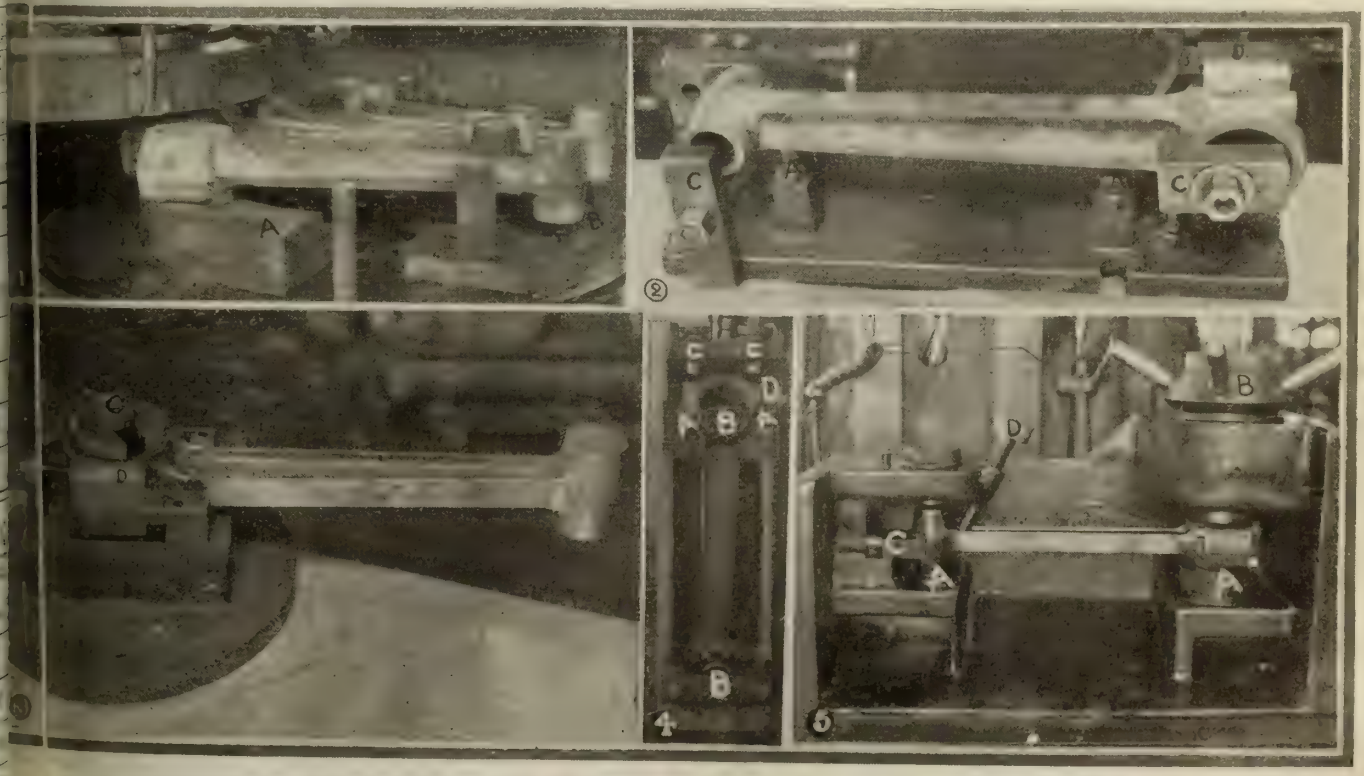


Some of the Principal Operations Including Grinding—Milling —Machining Register on Rod—Finishing Wrist-pin and Crank Pin Holes.

By ROBERT MAWSON

WHEN you manufacture connecting rods in any appreciable quantity, you must, to economically produce these rods, provide suitable jigs and fixtures. The data to follow shows how one firm manufactures marine engine connecting rods with considerable success.

The concern I refer to is the Murray & Tregurtha Corp., Alantic, Mass., who have been engaged in the manufacture of marine engines of various sizes, both light and heavy duty, for over thirty years. Their experience in this respect will no doubt be welcome.



The rods used on what are known as the high-speed engines are made of a machine-steel drop forging and are not all accurately machined, but heat treated to obtain a long-lived element in service. After the rod forgings have been tested for straightness the first machining operation is grinding the surface for the upper and lower boxes on a duplex hard surface grinder as shown in Fig. 1. The machine is provided with a magnetic chuck table which is used to hold the rods and fixture in position during the operation. The rods are placed with their large end resting on the block A, and the fixture is designed to accommodate 5 rods at one time. The small end is located on screws B, so adjusted that the web of the forgings will be parallel. The revolving grinding wheel is then fed across the faces on both ends and the machining operation performed.

Figs. 9 and 10. Milling and drilling the heavy duty rods.

The rods are next turned over and the opposite sides machined in a similar manner. An interesting feature of this fixture is the manner in which the forgings are staggered so that the wheel travels the smallest distance to finish the surfaces.

The fixture illustrated in Fig. 2 is used when machining the faces of the bolt and nut bosses on the rods. The forging is placed on the locating set screws A, and in such a position that the surplus material on the portions to be milled is equally divided between the guide pads B. The two clamps C are then tightened by means of the studs

Figs. 1, 2, 3, 4, and 5 showing grinding jig, drilling jig, etc. Refer to text for detailed information.

shown against the rod to hold it firmly in position.

A pair of gang milling cutters accurately spaced are then fed across the forging and the surfaces machined. The rod is then reversed and the bosses on the opposite side milled. This same fixture is also used for a later operation of parting the rod, the slot D being employed to locate the slitting cutter in the proper position in relation to the large end of the forging.

Machining Register on Rod.

The fixture shown in illustration Fig. 3 is used for machining the register on the rod which is the next operation. The forging is located by means of the steel blocks A, the inside dimension being the same as the space machined on the bosses in the previous operation. The set screw B is tightened which forces the element back into the locating mediums. The open washer shown is then slid under the stud; the nut C is tightened, holding the rod securely. This fixture is used on a Bullard boring mill. After the fixture is in position the register D is turned to the correct diameter. The rod is then reversed and located in a manner similar to that described and the surface on the under side machined in like manner.

The holes at the large or crank pin end of the rod are then drilled for the next operation and the jig employed for this work is shown in Fig. 4. The forging is again located by means of the two steel blocks A that fit outside the machined surface previously described. The lower end of the piece rests against a block, and as the upper end also fits in contact with a height pad the rod is in a parallel position when in the drilling jig. Straps and set screws being fastened against the forging force it back to the pads and also hold it securely in position. Two holes are drilled and afterwards reamed, the tools being guided through the long bushings C so that the holes will be in the correct alignment and also parallel.

This tool is also employed as the milling fixture when machining the dovetail in the rod after it has been cut apart. For this operation the section D is removed and as the rod is located and held in the large part of the tool the taking away of the piece noted does not impair its usefulness when used for the latter purpose. A set of gang cutters are then fed across the joint face and the recess machined on the large end of the rod held in the jig-fixture. A simple fixture is employed to hold the cap to machine, the mating surface on the joint, but is not shown.

The rod is then reversed, located in a similar manner, and the bosses on the reverse side machined. The cut away section D is a guide for the operator who feeds the table upward until the milling machine arbor comes in contact with this section. When the table hits this section the cutter is in the correct relative position for machining the connecting rod bosses. The position across is determined by means of the notch which may be observed at the inner edge of the height block D, this notch being the stop for the edge of the form cutter.

The fixture, Fig. 8, is used for machining the sides and top of the web of the rods. This tool is designed to hold two elements and these are located in vee blocks at the small end. The open washer and nut A, one for each rod, are then tightened to hold them securely in the fixture. The web section is machined, using an end mill for the operation. The purpose of this work is to obtain rods of more nearly equal weight, also for appearance. The rods are then reversed, located and held in a manner similar to that noted, and the reverse surface milled.

The operation described does not follow any particular sequence, sometimes being the last and at other times the second or third. However, the fixture, as will be noted, does not depend on the machined holes for locating, the rod being held by its outside surface.

Two operations will now be shown, depicting how the heavy duty engine rods are machined.

These rods are forged from solid bars of open-heart steel, and fitted with a marine type of bronze box which are held to the rods by means of bolts.

The forgings, the fixture being designed to hold two, are placed in the tool in Fig. 9 so that there is equal amount of surplus material at each side to be removed. The straps A are fastened down onto them by means of the bolts shown, thus holding the rods securely in position. The inserted teeth cutters B are correctly spaced to obtain the proper length and these are then fed across and the ends machined.

The rod is then placed into the jig, Fig. 10, being located by sliding the element until it comes against a stop at the lower end. The rod rests against steel blocks at the upper and lower ends as may be observed, the holes to be machined will be sure to be central with the forging. Two screws A hold the rod in position for the drilling of the holes. After one side has been machined the rod is reversed, being located and held

Continued on page 64

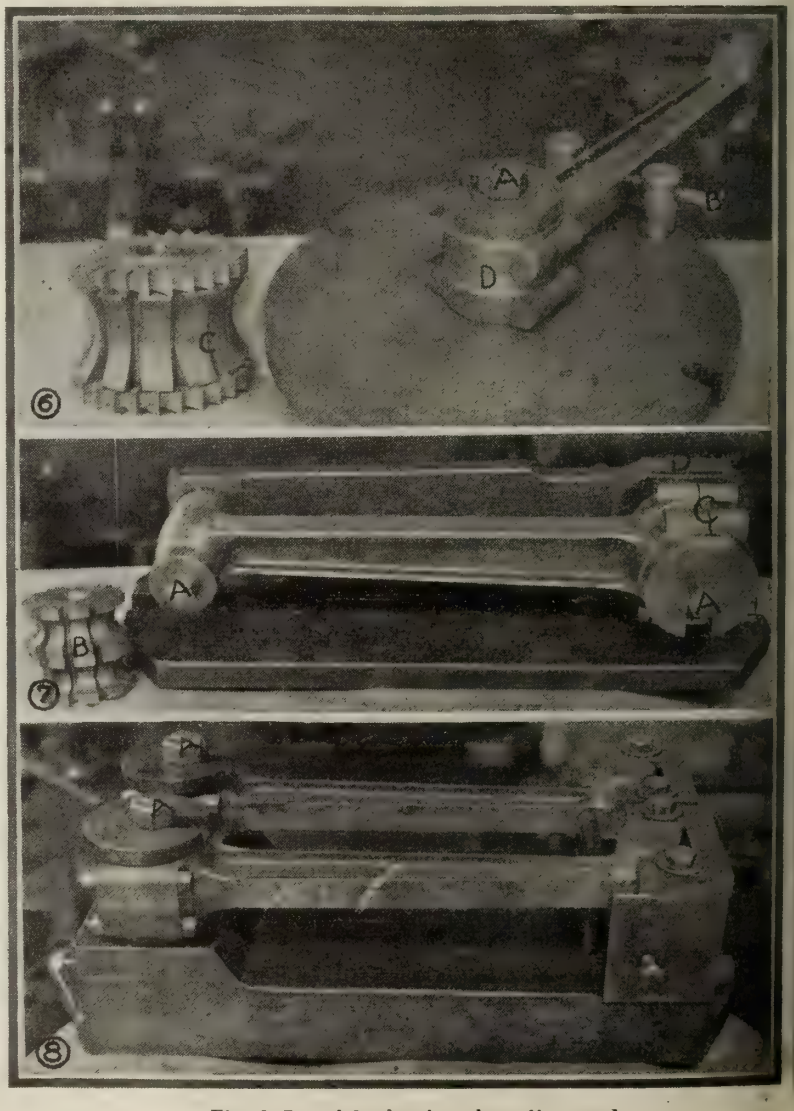


Fig. 6, 7, and 8, showing three jigs used.

Many Interesting Exhibits In Machinery Hall

No One Can Afford to Pass Up This Section of the Toronto Exhibition—The Various Exhibitors Have Spent Considerable Money and Thought on Their Displays

By J. H. MOORE

every exhibitor in the Machinery all at the Toronto Exhibition was sked what he desired most of all as the exhibition was concerned, uld loudly and emphatically state w Machinery Hall." There is no son but that the present edifice is quate. Not only is it too small, is so far out of date as to be y source of annoyance to those ex- itg. This is not said with the in- t of slamming the parties respon- for the exhibition, but rather to in in them the tremendous oppor- they are missing year after r Thousands of visitors refuse to s hrough the hall. Why? Simply e they think it will be very much me thing. This, of course, is not view to take of the matter, for ns are always made, and new ex- it are in place, but mechanics lves realize the limitations of h building. Suppose for a mom- new building at least three times e of the present one. Imagine nstruction after the plan of a one mill, with suitable transmission es. What would happen? Why, machine tool builder would be ng his neck to get in. Instead of they are almost breaking their year by year lugging heavy mach- nto the hall. At that it must not heavy or it will fall through the ut why go further, except to say that one exhibitor alone figures it will cost him at least $500 for the moving in and out of his exhibit. He is a local exhibitor at that. Many other firms would have larger machines in place were conditions suitable, and others again would have their machines in operation were facilities what they should be. The above is not penned in a knocking spirit, but rather in an attempt to create interest in a very necessary addition to Canada's greatest and best exhibition.

The exhibits this year are particularly interesting, and while we shall not attempt to give them in their order of importance, we shall endeavor to group them under various heads. Starting with machinery we find that

The P. B. Yates Machine Co., Hamilton

have a very nice exhibit which includes an open back nailing machine, containing several features of interest. They are also showing a single cabinet surfacer of interesting design, together with a type G-2, edging and ripping saw. Literature on all these machines is available. Naturally, we cannot go into mechanical details in the space at our command. In addition to the above they are showing a varied asortment of cutter heads, these including the square and round types, also special matching heads, jointer and ship lap heads. Another machine being exhibited is a type S-2 edge sander with tilting table, and this machine is so arranged that two men can work on it at one time. J. T. Donnolly and F. W. Mitchell are in charge of this interesting booth.

Messrs. Alfred Herbert Ltd.

are showing a very complete machine tool exhibit. Here are the various machines shown:—A No. 13 hexagon turret lathe, a No. 9 combination turret lathe, a No. 4 capstan lathe, a 16″ x 6 ft. Springfield 3-step cone lathe, a single spindle plain drill press, a No. 16 single spindle vertical milling machine, and a No. 1 Lumsden grinder.

In addition to the above they show another drill press with a geared spindle and automatic feed; a 16 x 2½ in. wet tool grinder , a ball bearing die grinding machine for grinding Coventry die chasers, a 3' 6″ radial drill, and a No. 2 Kearn's horizontal boring, facing, milling and drilling machine. Next comes a 13-in. Pollard pillar drill, a 22″ Pollard upright drill, a full display of tools, die heads, dividing heads, gauges, quick change chucks, drills, straight fluke drills, boring bars etc. They also show a new quick action vise, a universal vise, and a Herbert Morris two ton electric crane. In connection with the various machines, which are in operation, test jobs, or demonstration work is being run. One of these pieces, a distributor bush, is made from bronze and

A Typical crowd at the Toronto Exhibition.

is about 3½ O.D. and 5in. long over all. The work on this piece is turning, boring, facing, reaming, etc., and the complete part is made in 2½ minutes. The only way to understand this description properly is to go and see the piece being produced. Several men, all mechanics, will be on hand to answer questions and demonstrate the machines, these including Mr. Blair, Mr. Dowling, Mr. Thornton and Mr. Keith.

The A. R. Williams Machine Tool Co.

have a very fine exhibit including such tools as a C. M. C. shaper, a C. M. C. lathe, a small grinder, a sensitive drill press with sliding head, a C. M. C. column drill, a line of Williams' bench presses, a line of Starrett tools, a Williams' hand shaper, some C. M. C. wood working tools, and some bench grinders. They also show some gasoline torches, a small bench lathe, a very small bench drill press, and a No. 2B Hendey milling machine. The tools are nicely arranged and the majority of them are in actual operation. Mr. Cronk will be in charge.

Brown & Boggs, Ltd., Hamilton

with W. J. Graham in charge, have a very fine exhibit of presses and other metal working tools. Three inclinable bed presses are shown, from 1½ in to 4 in. strokes, also another solid bed press of 1½ in. stroke. All these presses have steel connections, not cast iron. A foot squaring shear, a steel brake for bending metals up to No. 10 gauge, also a complete line of tinsmiths groovers, rolls, etc., are shown. All presses are under power. This firm is featuring a new safety device, one of which is operated by electricity. Those interested in press safety will find that Mr. Graham will give them his best attention, as he is very much interested in this new safety device.

The Williams Tool Corporation of Canada, Brantford, Ont.

This company, formerly the J. H. Hall Co., have a very complete line of pipe threading machinery. Five machines are shown, these ranging from ¼ in. to 2 in. size up to the 2½ in. to 8 in. size. Large machines are made, but space does not permit their showing. This concern are credited with producing several of the largest pipe machines ever made in Canada, the size being 18 in. capacity. One of these went to the Crane, Ltd., Montreal, while another was sold recently to the Hydro-Electric Commission. Various photographs of the different machines are shown together with the potential die head used on such machines. This die has 20 streams of lubricant flowing on the work at all times. F. O. Chapman and R. Hall will be in charge of this exhibit.

Bond Engineering Works, Toronto

This concern are showing a full line of double power transmitting appliances, these including shaft hangers, spiro compression couplings, universal adjustable, ball bearings, friction clutches, Grundy flexible insulated couplings, ball bearing countershafts, pulleys, etc. A full line of stationary and swivel ball bearing truck castors is shown, also a double swivel truck castor. Transmission equipment in its many phases is shown, and Mr. J. D. Miller, who is in charge of this exhibit, will be assisted by Mr. Thring, and Stephen J. Miller.

Cowan & Co., Galt

are showing a varied line of wood-working tools, also racks containing wood-working knifes for planes and other such tools. A scroll saw is also in operation.

The Elliott Machine Co., Belleville

have a line of portable wood-working machinery, including scroll saws, floor and drum sanders, band saws, planers, etc. Mr. Glen Elliott, W. G. Elliott and Mr. Bradley will be in attendance.

The Webber Machine Co.

have a varied exhibit, this including a cylinder grinding machine as used on automobile work. They also show examples of work performed on various parts of an automobile such as pistons, rings, pins, drive shaft gears, etc. The reason the latter are shown is because they handle automobile repair work of all kinds.

The Cleveland Pneumatic Tool Co., of Canada

are showing a very complete line of pneumatic tools. These include chipping hammers and riveters, grinders, sand rammers, caulking and beading hammers, breast drills, rock drills, manifolds and all types of air hose couplings. They are featuring a manifold installation which shows the use of their two or three way fittings. All valves and couplings are connected, and even the tools are in place. This installation shows clearly the many ways in which such tools can be connected. Air drills of various kinds are shown, also a varied line of valves, armoured hose, etc. C. D. Garner, Canadian manager, A. W. Hughes, Toronto office, and R. E. Johnson are in attendance.

The Canadian Ice Machine Co.

have an excellent exhibit of refrigerating machinery, supplies, and materials. They show a double pipe ammonia condenser; a centrifugal motor driven brine pump; a York double cylinder ice machine; an oil trap, bent coils; a sheet of pure compressed cork, and other supplies in this line. Mr. Haine and P. G. Hender will be at this booth.

Jones & Moore Electric Co., Ltd., Toronto

are showing a varied line of motors ranging from 1-6 h.p. to 25 h.p. A shoe repair shop outfit in operation is also shown.

The Lancashire Dynamo and Motor Co., Toronto

are showing a complete line of motors from 1 to 25 h.p. A slow speed motor for commercial sewing machines is shown, and all motors are equipped with ball bearings. A feature of these motors is that they only require greasi twice a year. Motor starters a shown, also a disassembled mot which gives visitors a chance to see t interior parts. Various photographs installations are included in this e hibit. Mr. Powell, Mr. Steele and M Adams are in attendance.

Simplex Floor Finishing Appliance C Montreal

are showing a floor surface planer, al a sand paper machine for the sar purpose. These machines weigh in t neighborhood of 250 pounds, and t planer has a special feature insomu that it has curved blades, and is easi adjusted for various depths of cu Floors can be completed right up to t edges with either of these machine Mr. Ross, Mr. Grafton,and Mr. Vero neau will be at the booth. Canadian Mach inery was informed that these machin are completely made in Canada, ar that the hope of the exhibit was to i terest agents throughout the country these machines. In addition to t machines a varied line of floor polis ing materials is shown.

The United Shoe Machine Co.

have a full line of shoe repairing mach inery. The first machine as made t them is shown also the latest type now equipped with ball bearings. Th comparison is rather good. They als show a gasoline engine which is ofte used as a driving medium where ele tricity is not available. Mr. Hanson is i charge.

Superior Wrench & Tool Co.

are showing a varied line of patente wrenches.

P. B. Wallace & Sons

are displaying a complete line of sho machinery such as stitchers, roughers molders, etc., etc.

Railway & Power Engineering Co.

are representing a varied line of rail road and power equipment this includ ing armature coils, car ventilators, lo comotive sanders, electric sanders, lin material, trolley wheels, soldering ap paratus, car seats, seat covering, an in fact a full line of railroad supplies Mr. Foreman, Mr. Mitchell, and Mr Lyre will be at this booth.

The Dominion Steel Products Co., Brantford

have an interesting exhibit. They hav a 75 K.W. 375 r.p.m. high compressio oil engine in actual operation, and thi is said to be the first Diesel engine com pletely designed and built in Canada Mr. W. W. Brown, the designer, gave Canadian Machinery a complete descrip tion of the engine and while one can not go into a full talk on the matter i this small space, we can say that th exhibit is well worth a visit. Each cy linder is identical in assembly, and in terchangeability is an accomplished fact The writer saw the arrangements made and if desired one can disassemble any unit without disturbing its neighbor Even the governor and other smaller parts are arranged on the same princi- ple. The engine is very compact and is

completely self-contained. They are said to be fully efficient under both steady and variable loads, this being of considerable importance to any heavy duty engine. The electric generator is, as stated before, part of the complete outfit, and the crane can pick up the complete self-contained unit and place it into position wherever desired. Full details are given in the literature, which is given to those interested.

In addition to the engine, the concern are showing a complete line of cast iron and steel chucks of the design which has already been explained in our columns. These chucks are very neat and their strength is already well known. A varied line of Darling valves is also shown, this company being exclusive Canadian agents for this line. The valves vary in size from 4 in. to 24 in., and hydrants of the Darling type are also shown. In fact a section of one hydrant is supplied. The exhibit is rounded out by the showing of a motor driven two stage auxiliary air compressor. All these various items have to be seen to be appreciated, and either Mr. Brown or the other gentleman in charge will be glad to explain matters in more detail.

The Dodge Co., Toronto

have an interesting exhibit showing their line of wood, steel and iron pulleys, both solid and split. Hangers, pillow blocks, and bearings of all kinds are shown together with solid and split clutches, floor stands, wall brackets, conveyor rolls and every conceivable type of equipment for transmission purposes. W. B. Burrows; E. A. Foley, and S. M. Bowen will be in charge of this booth.

Welding Exhibits

The Carter Welding Co., Toronto

are showing a very complete line of Rego welding and cutting torches. A lead burning outfit, a balloon filling outfit, and racks containing all sizes of torches, regulators, filling rods, and general welding supplies are shown. Carbon burning outfits are included, and in fact the welder has been considered from all angles in the preparation of this exhibit. Mr. Carter and Mr. Sorely will be pleased to demonstrate any of the articles displayed.

Prest-O-Lite of Canada, Ltd.

with Mr. Gimble, Mr. Smuck and Mr. Judson in attendance, are showing a complete line of welding torches and general welding apparatus. These lines include soldering irons, soldering torches, brazing torches, small tanks for trucks using acetylene, preheaters, welding torches and the various filler rods used in welding. They also show how small towns can be fitted up with acetylene lighting where electric power is not available, or in case of unforseen trouble. They also show a cast iron cutting torch of notable design.

The Davis-Bournonville Co., Toronto

have a very fine exhibit of portable welding and cutting plants. A 50 pound capacity portable generator is shown, also a radiograph and an oxygraph. They have a full line of welding torches and are showing the non-flash back feature. They also have a flashlight generator, and have various men demonstrating the various exhibits. J. F. Crowley will be in charge, and will be assisted by F. Grimmer and H. L. Wilson.

L'Air Liquide Society

are showing a varied line of oxy-acetylene apparatus, this including gas cylinders of various sizes, torches of various kinds and complete outfits ready for work. A cylinder has been cut in half and those not familiar with the interior construction and filling of such a tank should view this sectional cut tank. Various men are in charge of this exhibit, and any of them will be glad to demonstrate the line displayed.

The Canada Carbide Co.

not only show a variety of their products, but have a model electric furnace installed. In addition to the above they are showing a very novel toy cannon which works by means of a granulated carbide and water. The gun will be demonstrated to anyone interested and the principle involved is worth while. Lantern slides showing the manufacturing process at Shawinigan Falls, also form a part of the exhibit. Mr. A. McMillan is in charge of this booth.

Miscellaneous

The Canadian Link Belt Co., Toronto

This company is showing a rather interesting installation, which they call "A Silent Chain paradox." A disk with nine slots revolves in front of a chain drive arrangement, and to the casual spectator certain of the chains do not appear to be moving although they are actually travelling at the rate of over 1000 ft. per min. The secret is that the sprockets used to drive these chains are all certain multiples of nine.

In addition to this drive, racks are shown which contain different kinds of malleable iron and steel chains, buckets, etc. There is also a rack containing their silent and roller chains, also photographs depicting the chains being made at their Toronto plant, also others showing actual applications of such chains. J. S. Stewart, E. C. Burton, R. C. Turner, and F. C. Conant are in attendance.

The Chapman Double Ball Bearing Co., Toronto

have a very neat installation, showing, as they term it "a near attempt at perpetual motion." This shows an arrangement of pulleys large and small, all mounted on Chapman bearings. A 1-20 h.p. motor drives the complete arrangement and the belt used is simply a stout cord. This exhibit shows clearly how friction can be practically eliminated by the use of proper bearings. In addition to the above a varied line of pillow blocks, hangers, typical line shaft drive, etc., are displayed. The Tranco elevating truck equipped with ball bearings and made by this concern is shown, also a style of roller bearings particularly adopted to the front axle of Ford or Chevrolet cars. Mr. Murray, C. J. Hocken, or G. Cole will be pleased to have you call.

The International Nickel Co.

have a very complete exhibit in the process building. The best method of describing the booth would be to itemize the various articles shown. The uses of "Monel" metal are featured, the following applications being exhibited. A steam table as used in hotels, cafeterias, etc., with a monel top; a sterilizer, a meat slicer, milk dispenser, all equipped or trimmed with monel. Then there is a 6" crane gate valve for superheated steam that is trimmed with monel, also a valve cut through the center for demonstration purposes. Around the booth is shown some representative monel castings rough machined, and polished. There is also a display of polished monel sheet, and various sizes of monel rod, tubing, etc. Chains, cutlery, screening, wire, and other products made from this metal are shown. Various pieces of electroytic nickel are displayed, also some samples of nickel salts, nickel shot, anodes, welding rod, monel bells, welded tubing, etc. As one of the attendants pointed out to Cana-

dian Machinery, "Monel" is not a precious material as some think, but is a commercial metal that can be rolled, drawn, welded, cast, forged, brazed, soldered, machined and spun. C. A. Richardson is in charge of this interesting exhibit and will have E. A. Turner and G. M. Crossgrave assisting him.

Over in the process building the

Canadian Hanson & Van-Winkle Co., Toronto

have a very interesting exhibit. A complete plating set is shown, this including a motor generator set. All fittings are included and the compactness of the set is very apparent. In various portions of the booth are racks showing anodes, polishing wheels, canvas wheels, brush wheels, industrial brushes, plating and polishing chemicals, etc. A cleaning barrel and tank are also included, and of course the "Royalite" cleaner is featured. Mr. Elder is in charge.

Messrs Peacock Bros., Ltd.

have a very varied line this year including Weir boiler feed pumps, Foxboro instruments, Aldrich Vertical triplex pump, Hopkinson valves, Richardson automatic scales, a line of instruments made by the Precision instrument Co., and an interesting display of steam traps, radiator traps, and temperature regulators made by the Darco Co., Inc. They also show the Merco Nordstrom non-sticking plug valve which is something new to this section of the country, a simplex valve reseating machine, a line of safety lamps, a miner's air pick, and other varied lines. This is a very complete exhibit, and Mr. Kudera will be pleased to answer any question put to him.

The Black Donald Graphite Co., Calabogie, Ont.

are showing a complete assortment of their line of graphite products.

The Dunlop Rubber Co., Toronto

show an interesting exhibit of rubber belting, fire hose, etc. An installation of a Gibraltar conveyor under power is shown, this consisting of a large rubber belt to which cast iron buckets are fastened. Fire hose, garden and industrial hose are also part of the exhibit.

The Toronto Hardware Mfg. Co., Toronto

are showing a varied line of hot water tanks, elbows and fittings. It is a representative exhibit of such lines and Mr. Ince or Miss Hannon will be on hand to meet visitors.

E. Pullman Wipers and Waste Co., Toronto

are showing a full line of wiper cloths, knenser kloths, and mop cloths. The latter are featured because they come to the customer in large pieces allowing them to be cut up as desired. They are also very soft and absorbent, two essential features in cloths of this nature. Competent officials are in charge ready to explain the uses of the various kinds of cloths.

The Wayne Forge & Machine Co., Toronto

who are agents for the General Alloys Co., Chicago, are showing a line of industrial furnaces, carbonizing boxes, heat treating appliances, firebricks, steam boilers, etc. Literature on all the exhibits is available, and Mr. S. Watson and Alfred L. Watson are in charge.

The W. R. Sexton Boiler Setting Co., Toronto

are showing their line of Elkco fire brick, this including special as well as standard shapes. They also are exhibiting their nonpareil dumping grate bars, together with a few boiler settings.

The Geo. W. Cole Co., Toronto

are showing a very complete exhibit of their various lines, these including a miniature installation, boiler feeders, condensor traps, return traps, receivers, swing check valves, pressure reducing valve, etc. They also show a Kitt's pot trap, and a Kitt's pressure reducing valve. The exhibit is well arranged and G. E. Cole and J. E. Farrell will be in attendance.

Baines & David, Ltd., Toronto

are exhibiting all kinds of iron and steels, these being in the form of sheets, bars, etc. They are featuring the "Mowbray" line of tool steel, this being made in Sheffield, and they have a bar of 7" diameter material on exhibition as well as smaller stock in various forms. They are also showing their universal stair tread which is said to be non-slipping. J. S. Morrison and W. Jefferson will be in charge.

The D. K. McLaren Co.

have an interesting exhibit showing single and double belting and supplies for the textile trade in general. The belts include waterproof leather, balata, etc., and an interesting installation of two belts running through water is shown. Split pulleys, belt dressing, belt fasteners and other accessories are included. This booth is featuring a very neat case which contains a collection of card clothing belts for woollen and worsted carding. These show the different size and style used in the various operations and over 30 samples are shown. This in itself is worth inspection and W. S. Hamilton, who is in charge of the exhibit invites anyone interested.

Peckover Ltd., Toronto

are displaying a complete line of steel, including metal lath, plates, hoop steel, reinforcing sheets, bars, structural sheets, boiler tubes, and tool sheets. They also show the Feralum and Vulcanum slip roof tread. They are featuring the metal lath of which a great amount is being sold according to H. J. Peckover, and H. Raine who are in charge of the engineering dept of this booth. R. C. Peckover, J. G. Near and G. Jolly will be in attendance at the other section of the exhibit.

The Dominion Belting Co.

are showing a complete line of conveyor and transmission belting. This is the well-known Maple leaf cotton stitch belting. Belt fasteners, belt dressing and other supplies are also displayed E. Kinrade is in charge.

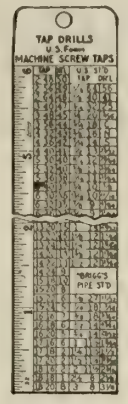
The National Electro Products

are showing a varied exhibit of their Hydrogen and Acetylene tanks, also a complete line of welding and cutting apparatus, supplies for same and so forth. A model sectional view of an acetylene cylinder is shown, also a portable oxy-acetylene outfit, together with a portable Hydrogen cutting outfit. A carbon removing outfit also a lead burning equipment are displayed. Mr. Burns and Mr. Copeland will be at the booth and demonstrations will be given upon request.

Canadian Atlas Crucible Steel Co.

have a good exhibit showing their line of tool steels in various forms. The steel is shown in bar form, also as used for axes, cant hooks, reamers, drills, milling cutters, dies, cutlery, auger bits, chisels, etc, etc. Mr. Ley, Mr. Rundle and Mr. Fraser are in charge.

The Clipper Belt Lacing Co.



have a neat exhibit showing the many applications of their well known product. Mr. Logan is in charge of this booth and claims he is ready to meet all comers.

SOMETHING NEW IN WINDMILLS.

Many attempts have been made to solve the problem of efficiently utilizing the winds as a means of generating electricity. The difficulties arise from the extreme variations in the force of the wind and from the liability, even in windy regions, to periods of calm during which no power at all can be obtained. These conditions suggest that wind power should be used only as an auxiliary to some other source of energy, such as the burning of coal or oil. Now that fuel of all sorts has multiplied in price there is all the more reason for considering the possibility of turning the wind to account. Hitherto the usual plan has been to use a large slow-speed windmill to drive a dynamo at a high speed through gearing—a rather wasteful arrangement. During the war, however, there was in Great Britain a remarkable development in the design and construction of small high-speed dynamos on aeroplanes. These dynamos were direct-coupled to propellers or rather "impellers," driven by the wind created by the aeroplane in flight. A British firm has devised a scheme for fitting three or more of these wind-dynamos on the swivelling top of a vertical pole; with a vane to keep them in position against the wind. Each equipment gives 60 watts, and the arrangement forms a cheap and efficient auxiliary to the ordinary country-house lighting installation. The energy produced is, of course, stored in accumulators in the usual way. The operation of the plant is entirely automatic and it is so light and simple that it presents no obstacles in erection and maintenance.

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

The contest page for August 11th issue was set up, yet by some mysterious process it got mixed in with the material for another paper, and for the time being was lost. When found, it was too late for use as the issue had gone to press. For this reason we will award two scales to the winners of the August 18th contest.

CONTESTS FOR SEPTEMBER 1st ISSUE

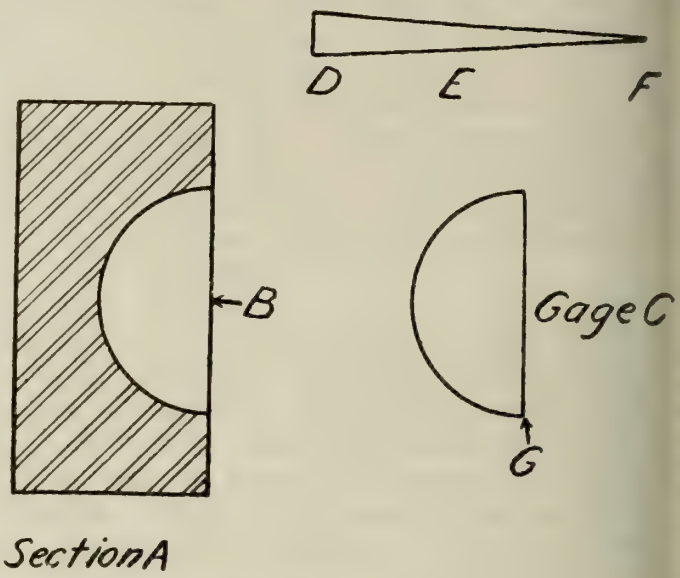
Contestants are required to write us, stating to which advertisements we refer in this number.

1—A case where a hammer only is used.
2—Something that grows larger every year.
3—A product with hand or power feed.
4—Something that was thoroughly investigated.
5—How to get away from continual attention.
6—Something to watch for.
7—A product that can be secured throughout the world.
8—What to do if your regular business is dull.
9—Something that is portable.
10—How to avoid trouble.
11—Something that is accurate and easily operated.
12—A difference of importance.

By an accident, the contest page for August 11th issue was omitted, so that no comments are necessary in this panel.

Closing Date for This Contest is Sept. 22nd

WHAT OUR READERS THINK AND DO



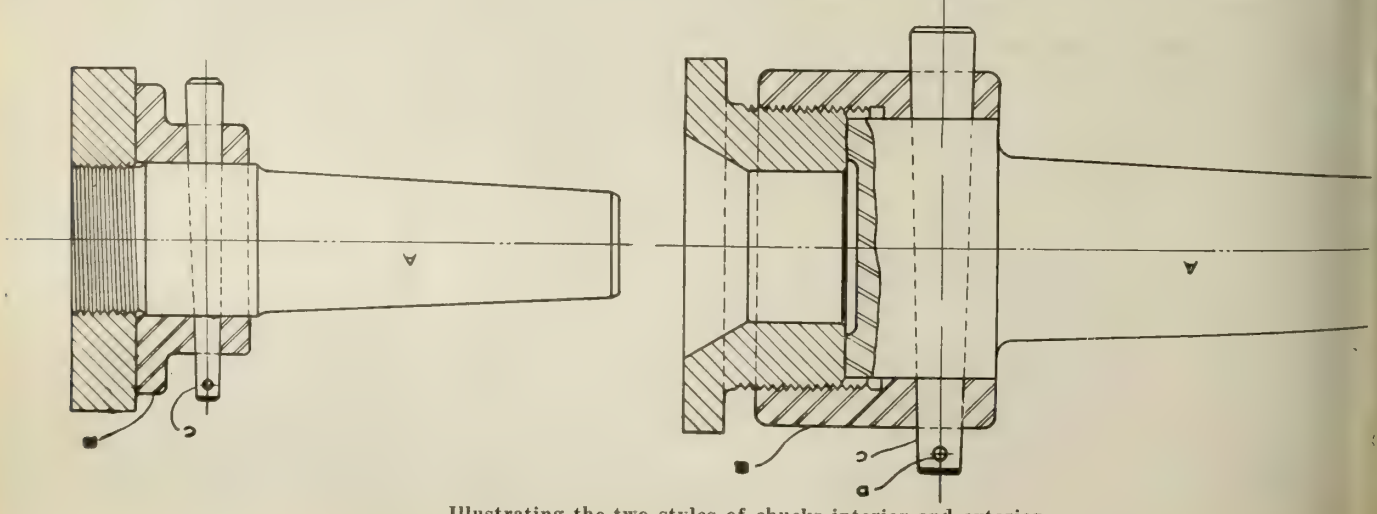
TWO STYLES OF CHUCKS

By J. Homewood

The two chucks shown, illustrate where the principle of the wedge plays an important part. The interior chuck is used on internally threaded work that is faced and requires another operation, requiring another setting to complete the piece. In order to do this operation on a solid arbor, where the face of the work would bind against the shoulder, the amount of effort necessary to remove the work after it is finished invariably results in damage as well as delay. The spindle (a) is hardened on the wearing end, in this case the threaded end; the sleeve (b) is also hardened on the face that bears against the work and ground in position. The taper pin (c) is driven to the tight position before the piece is screwed up to it. Upon the completion of the work the taper pin is slightly tapped to loosen it and the piece of work will be easily removed. The small pin retains the larger one.

The Exterior chuck is used on work that has been threaded on the outside and which also requires another operation to be performed and maintaining accurate relation to the first. The principle of this chuck is identical with that of the interior chuck, the loosening of the taper wedge releasing the thrust against the two faces of the work and the chuck.

The U. S. Light & Heat Ltd., has been incorporated to manufacture machinery, tools, etc., for generating light, heat, power, etc. The capital stock is placed at $40,000.



Showing how the radius was turned.

TURNING A RADIUS

By G. RUSSELL

A few weeks ago a job came into the shop to cut out a piece of steel shown in cross section A. The lathe was the only place available, so to save time in making a forming tool we used the following method. The work being roughed out in the usual manner we clamped the gauge C to the tail stock spindle taking care to have its centre. Using an ordinary boring tool and finding a piece of thin metal as shown at E we clamped the one end D in the tool post, setting the boring tool until it touched the point B. Then, bending the piece of metal until the point F just touched the gaug at G, we started the machine wih slow longitudinal feed, and worked th cross feed by hand keeping the point just touching the gauge all around t the centre line. This we repeated unt the job was to size, taking the hig spots off with a scraper. By this mear the work was finished in almost the tim it would have taken to make the formin tool.

Yukon and Federal authorities a carrying on investigations regarding tl construction of a 500 mile road fro Camp Mayo to Fort Norman.

Illustrating the two styles of chucks interior and exterior.

ROUTING THE WORK

THE up-to-date plant gives special attention to routing work. For example, F. L. Prentiss in a recent issue of "Iron Age" says that in a new plant at Youngstown, devoted to pressed steel work, everything has been planned for handling a large volume of material and handling it rapidly.

Tunnels under the press shop floors for handling both products and scrap reduce the amount of trucking on the floors of the shop by one-half, and congestion around the presses is avoided. As a general rule, the movement of material on the press shop floor is in a forward direction and the back-tracking will be done in the tunnels. There are five buildings, these consisting of a receiving building extending the length of the plant with four parallel connecting manufacturing buildings at right angles to the receiving building, and connected with it. The maintenance department, including the machine shop, tool room, die storage room, millwright department, and the factory offices, are centrally located in the open hollow square formed by the five main buildings.

Two tunnels are located under the heavy press shop, one directly in front of each line of heavy presses. An opening is provided in each press foundation which forms a recess in the tunnel, and in these recesses tote boxes are placed for handling parts or scraps which drop from the press. Hand or storage battery elevating platform trucks will handle these tote boxes to the press room floor and deposit them beside the press for the next operation, or will take them through the tunnel to the pickling department, which is located in the central court. Two elevators connect the tunnel with the press shop floor.

RECOGNIZING MERIT

Speaking on the subject of "Foremen," Wm. A. Ahern, says in "Industrial Management," that the qualifications of a foreman in a machine shop are three: knowledge of his trade; ability to route work and keep it moving; and ability to get along with his help so as to keep up production while keeping down labor turnover, the thing which is so costly to the factory through the necessity of continually breaking in new men who are not producers until after an unprofitable period of weeks or months.

"Notice that the second point calls for production" continues the writer, and that it does not specify that the foreman shall get his production by any one method; the method he chooses is up to him; and the third point likewise calls for getting along with his men, and does not specify any limitation as to how he shall get along with them. Perhaps he is not the kind of a chap who holds out his hand in greeting and slaps the new man on the back and tells him funny stories like a salesman,—that is only one method of getting along with men and it would not always work in a machine shop. What men want is results to themselves,,—they want things, conditions and advancements, not words or "bull." If you can give them the things without the words so much the better; that is one way of getting along with them, with an efficient use of speech. The best foreman I ever knew was a Bohemian who seldom said a word in the shop, partly because he talked with an accent. The time he might have otherwise used in talking he turned over to his brains and used them in thinking. And this is how he worked:

When you as a new employee first came in to the shop he heard your story as to what you could do, looked you over, looked through you, and then gave you a piece of work which had certain processes of more or less difficulty. Then he forgot all about you until you brought the finished work to him. He looked it over; measured it. If it was extremely bad he would say, without any expression on his face: "That is not very good." Then for your next job he would set you roughing out about three-quarters of the stock on a casting for a jig,—something that would not delight the heart of a mechanic.

If you brought him a finished piece that was fairly true to dimension but had a scratch on the surface, he would say nothing. But he would give you for your next job filing burrs from an endless multitude of milled pieces to teach you the value of smoothness. Suppose the job he gave you was well done. Then he wouldn't say anything either; but your next job would be a little bit more difficult and of a little finer grade of work. This is what a mechanic wants. If he is an old hand at the business he wants to have his skill recognized by having you depend upon it for a higher class of work. If he is a new man or an apprentice he likes to have the opportunity to do better and better work so that he will learn all the quicker. So every man went away from that foreman bench knowing that his accomplishme had been recognized, though the forema hadn't said a word.

INTERESTING DISCOVERY.

Great interest was caused recently London by a demonstration, given b fore the Institution of Electrical Engi eers, of a strange phenomenon alleg to be absolutely new to science. Wh an electric current is passed throu a half-conducting material, such as thographic stone, in close contact wi a metal, the metal and the stone sti together with a force which is out proportion to the strength of the cu rent passing from one to the other. T demonstrators, who came from Sca dinavia, showed how this phenomen could be applied in making a lou speaking telephone. By its help th made a violin reproduce music play in a distant room and "speak" wor spoken into a distant telephone tran mitter. The demonstration was, ho ever, followed by proof that the phen menon had been discovered many yea before in Great Britain and its applic tion to telephony had actually been d scribed before learned societies and in popular encyclopedia. The discovery Scandinavia was therefore a re-disco ery and the incident suggests that t past records of British research and i vention may contain more hidden iter capable of practical development in t light of the fuller knowledge now ava able.

REASONS FOR HEAT TREATING.

There are two reasons for heat-trea ing cast iron. The first is for the pu pose of breaking down the intern stresses that exist in the casting. accomplish this the casting is heated to 550° C., and kept at that temper ture for several hours. The exact tin necessary depends on the thickness the casting. The operation is oft practiced on pieces to be partly machi ed such as gas-engine cylinders, etc. T castings are placed in either a cast-ir or steel box, and lightly dusted ov with powdered coke or charcoal. T box is then firmly closed and careful luted up with fireclay. The purpose the second method is for softening t metal, especially castings of thin se tion which are liable to be chilled. F arriving at this result it is necessary carry the heating of the piece up 850° C. for one or two hours.—"Fo derie Moderne."

DEVELOPMENTS IN SHOP EQUIPMENT

SMALL ELECTRIC WELDER

Buckly, Saunders & Co., 8 Prince's St. Westminster, England, have placed on their own market a portable welding machine. The apparatus consists of two main parts—the welding machine proper, and a controller which contains mechanism to regulate automatically the stages of a welding operation. The tool includes two electro magnets, which enable it to cling tightly to a body of iron or steel and do its work on it in any position. Between the magnets is a chuck, operated by a solenoid, to hold a stud or other circular object which is to be welded on. A third adjustable leg is provided to steady the tool on a curved or irregular surface. When a stud has to be welded to a plate the tool is merely pressed against the last, and a switch closed to bring the magnets into action. A spring pushes the stud hard against the plate, so that when welding current is turned on the circuit is complete. A solenoid, acting against the spring, withdraws the stud and strikes the arc between it and the plate. At the end of a sufficiently long period the solenoid is short-circuited and the spring presses the glowing end of the stud against the plate with sufficient force to ensure a weld. The controller mechanism regulates the time during which the arc is in play, and the operator's part is limited to closing the switch and so bringing into action the clockwork which, by means of cams and subsidiary contacts, ensures that certain things happen in a certain order. The "timing" of the weld can be adjusted beforehand to suit the particular job.

DOUBLE SEAMING MACHINE.

The Niagara Machine & Tool Works, Buffalo, N.Y., have placed on the market a machine for double-seaming simultaneously both ends of sheet-steel barrels or drums. The machine is handled by only one man. It is capable of seaming barrels from 18 to 36 in. in diameter and from 20 to 45 in. in height and made of No. 12 gauge or lighter steel.

When operating the machine, the barrel, with the heads in place ready for seaming, is rolled in on runways onto the horizontal bars. The barrel is located on the supports by stops, and is raised in line with the chucks by means of a treadle. The column is then moved into position by the hydraulic cylinder, which is operated by means of a hand lever. The pressure thus exerted clamps the barrel between the two chucks, forces the heads into their proper position, and holds the body while the seaming operation is being performed.

The seaming operation is started by means of a hand lever which releases a positive instantaneous clutch and sets two camshafts into motion. The curling rolls are automatically brought down to the work, and curl the seams. These rolls then recede, and the flattening or finishing rolls move into position and finish the seams. The machine makes a predetermined number of revolutions, to allow sufficient time for the proper performance o f the work. Only about forty revolutions of the barrel are required to complete the seams.

WELDING MACHINE

The American Electric Fusion Corporation, Chicago, Ill., have marketed a vertical spot welding machine.This type of welder is built in four sizes, and the nominal throat sizes are 11, 24, 36, and 48 in. In each case however, the actual throat depth exceeds by about 8 in. the size stated. The column is of box-form and incloses all high-voltage parts of the electrical mechanism, including the switches. The lower horn support is a box-form casting that slides on ways bolted to the front of the column. The upper head is so constructed that it may be completely turned around. The welding points are copper die-castings.

SQUARE AND BEVEL GAUGE

A combination die square and bevel gauge for the laying out of tapers and angles on dies and similar work, has been placed on the market by the Scalbom Manufacturing Company of Chicago, Ill. The body of the tool is held against the work while the blade is swiveled to the desired angle. The blade is clamped in position by means of a locknut. All parts are of steel and hardened, the blades being provided in various thicknesses.

A Regrettable Incident

FROM causes yet unknown the British airship R-38, which had been christened ZR-2, before her inclusion in Amer- air fleet, broke in two while flying over Hull, England, ugust 24th. The machine was on a trial flight before be- anded over to the American crew, who were to have nav- ed her across the Atlantic. There is no need to go into letails of the trial trip for all this has been carefully re- d in the various newspapers.

e chief point of interest to aeronautical engineers, is Vat Caused the Disaster?" Some hint at faulty construc- of the steel work; others claim that fire occurred; while again content themselves with commenting upon the handling of the ship, even after the accident occurred. vestigation will no doubt be held, and from the import- of the event, it is likely to be a thorough one. It is to ped that a correct solution of the cause of the disaster will rived at so that another dirigible of like proportions can ilt which will successfully accomplish what the ill-fated ner of the ZR-2 hoped for.

hen we consider the proportions of the dirigible which has been destroyed we cannot but marvel at the rapid strides h have been made in this branch of aeronautics. The th of the ZR-2 was 695 ft. or 50 ft. longer than the R-34. s apacity was 2,700,000 cubic ft., and if altered for com- al purposes it was capable of handling 50 tons. It had a h of 2,100 having six engines of 250 h.p. each. It was le of a cruise of 6,000 miles, and if it had come up to the ner's hopes, it could have carried 40 passengers and two f freight in a non stop flight from England to Egypt in rs. A radio set was installed, having a sending radius 0 miles, also a wireless telephone set. The armament ted of fourteen Lewis guns, one 1-pound automatic gun, 20 pound bombs, and eight 230 pound bombs.

e years ago the airships then in vogue were considered s. but in comparison with a ship such as the ZR-2, they e the small tug boat alongside of the huge liner Levia- An airship in the earlier days was practically at the of every wind, and had no means of knowing when a was approaching. To-day, however, with wireless at h stage of development a ship such as the ZR-2 can hear approaching storm, and in fact this ship did receive of such a storm on her trial trip. The crew can also nicate with those on land, reporting progress, etc., etc. pite of this accident, which will create a stir all over the l the leaders in the movement for larger and safer dirig- ust not falter. The loss of life is much to be regretted, story is merely repeating itself, for science will always d the sacrifice of many lives before an invention of this an be perfected. Those who perished on the ZR-2 will own in the pages of history as heroes and pioneers who rying to accomplish something greater than had been o attempted.

Signs Of A Revival

THE news from the various freight markets of the world show that there is at last some signs of that revival in the shipping trade, that has been earnestly looked for. This follows the resumption of work by the coal miners in Great Britain, and the progress of the price of this fundamental necessity to industry to more reasonable levels. Shipowners are once more enabled to send their vessels on long voyages in ballast, to bring return cargoes home, without the whole revenue of the voyage being eaten up in fuel costs. However, the price of coal has not yet reached the level where it can be exported to any great extent, and the fact that European countries have on hand large stocks of American coal that were shipped during the strike also militates against export of British coal for the time being. This will adjust itself in time, and there is little fear of American competition in this trade once conditions are normal. Another faint hope arises, in contemplating the appalling condition of Russia, that the powers there will be at last convinced that their effort towards a Communistic state has proved abortive, and that agriculture and industry may once more be resumed in that tortured land.

"Hold tight. You'll go up in a short time." Some good advice to the business world from Racey.

MARKET DEVELOPMENTS

The Hopeful Feeling Continues in the Market

Although Business Cannot be Said to be Rushing There is a Decided Spirit of Optomism Existing—Several Reductions in Prices Have Been Made.

THE market situation continues to improve. The movement may be somewhat slow but nevertheless it is there and is getting better as time goes on. Although the past week has shown a slight slackening off in the demand upon the steel mills, there is nothing in general business that would reflect unfavorably in the steel industry. It looks as if the winding up of the regular vacation period is responsible for the change.

The Toronto market shows several reductions this week. Chain blocks are down 12½ per cent; galvanized sheets have been reduced $8 per ton and where a large order is in sight, machine tool manufacturers will shave their schedule prices to the dealer so that he can close the business. One tool manufacturer has announced a further reduction in prices of its machines.

Tubes are moving at nice speed, also metal lath. Re ir work in the former case, and building activities in the la r are said to be responsible for the spurt. Scrap metal rem is at the bottom of the heap. There is nothing being done i the prospect for future business is none too good.

The situation in Montreal is improved over last w k. Activity along the harbor is very marked and railroads re t an increase in the movement of freight. A gradual impr - ment is looked for from now on. Building seems to be pic g up one job costing nearly $500,000. Machine tools are y dull—dealers and manufacturers preferring to quote on l orders, rather than abide by a general price list. The pig n situation in this market also seems to be improving.

SHEETS TAKE A SUDDEN DROP PIG IRON PRICES STILL ADVANCING

PITTSBURGH, Sept. 1.—Demand for steel mill products, on the whole, has decreased in the past week or ten days, after fully a month of continuous though slow improvement. There is no particular reason for the backset, unless it is due merely to the winding up of the regular vacation season. It is a fact that the steel market has usually been particularly dull in the last fortnight of August, the explanation commonly given having been that vacations were running especially strong.

Certainly there is nothing in general business that would reflect unfavorably in the steel industry. General business may not have improved much, but it probably has improved some, and it certainly has not grown worse. Nor can it be thought that steel buyers overbought recently, for all the buying was plainly for the purpose of supplying immediate necessities. Nor, again, can it be said that buyers of steels have lost any "confidence." They never had any confidence. They were buying, not because they had confidence, but because they absolutely required the steel in order to stay in business.

September may be confidently expected to bring an increase in buying, though not a great deal is expected. The present state of general business ought in the long run to give the steel mills an operation of 30 to 40 per cent., this to increase whenever general business improves, when the railroads get in position to buy and when there is freer inception of investment projects involving construction. The last named things are not expected this year, February or March being the expected time for such additional improvement.

The steel mills have been operating at about 25 per cent. of capacity in the past couple of weeks, this comparing with a rate just under 20 per cent. at the middle of July. While buying has been a trifle slacker in the past ten days mill operations are not likely to decrease, at least by a noticeable amount.

Steel Prices.

In the matter of prices of finished steel products, sheets took the centre of the stage in the past week, owing to there being a clear cut decline. Steel prices in general have been showing no more than a slight downward trend in the past few weeks, and the definite decline in sheets was due to two things, that there was a demand sufficient to cause sharp price competition, and that sheets have always been a particularly competitive commodity, due partly to there being so many sellers, and partly to the peculiar personality of some of these sellers. The history of the sheet decline is somewhat interesting. By A ust 1 the regular market had go n down to 3.00c for black and 4.00c galvanized. In the early part of Aug t these prices were being shaded by a few mills in the case of especially sirable orders, but the general ma held at 3.00c and 4.00c. Just after middle of August a Wheeling dist producer began openly quoting 2.75c 3.75c, equal to a cut of $5 a ton. F other independents promptly follo suit, and then the Steel Corporation duced its prices. Judge Gary mad public statement on the subject, rei ating that when important indep ents cut prices the Steel Corpora follows, but that the corporation n takes the lead or originates redu prices. The new prices for sheets probably below the cost of produc to the average mill even if the mill w given a moderately full operation. the other hand, bars at 1.75c and sha and plates at 1.80c, which are g prices now, would give a mill a li profit, perhaps a fair profit, if it full operation. With operations of to 30 per cent. all steel prices t days are below cost.

It is plain that there is still m liquidation to be effected among ma facturing consumers of steel. Th are still stocks of manufactured go to be distributed, but the stocks of s are in most cases down to a low po The agricultural implement industry

particular has large stocks of finished goods, but these are expected to move now, as farmers are realizing on crops and the crops were raised at a very low cost. The implement trade furnishes a particularly strong illustration of the reason for demand on the steel mills being so light at this time, for in normal years the new manufacturing season with the implement trade begins about August 1, whereas this year the implement factories have not even bought steel to any extent.

The advance in pig iron prices is really beginning to amount to something. The Chicago district sellers are up to $20, furnace, having made their lowest sales at $18, some two or three weeks ago. Buffalo is up $1 a ton. Eastern Pennsylvania shows no improvement in prices thus far. In the Pittsburgh valley market there is an advance in basic and a slight advance in foundry iron. Basic had gotten down to $18, valley, equal at $19.96, Pittsburgh. Then all, or nearly all, the sellers concluded that they would ask $20 furnace on the next inquiries. This did not work out altogether, but a 2,000 ton transaction has just gone through in which the buyer, a steel interest in the immediate Pittsburgh district, paid $20.96, delivered, equal to $19 f.o.b. valley furnace. The seller had less than the valley freight to make the delivery, and thus realized more than $19 at furnace. Foundry iron is quotable at $20, valley, or a 50-cent advance. Bessemer remains at $20, valley, and a 300-ton sale was made in the last few days at this figure.

Demand for coke has been looking up in the past two or three weeks, as here and there a furnace has occasion to resume operations, chiefly on account of depletion of stocks, rather than on account of increased demand. The Connellsville coke industry is not getting much out of the improved demand, however, the reason being that by-product coke stands in the way. On account of the value of the gas and other by-products, a by-product plant can pay for coal a better price than the Connellsville operator realizes for the coal when sold in the form of coke, and still undersell Connellsville on the coke. Connellsville furnace coke is not over $3.00 per net ton at ovens, and 1½ tons of coal are required for a ton of coke. At $2 cents to cover the actual cost of coking, the operator would be getting $1.50 a ton for the coal, yet by-product plants pay $1.80 and even higher for Connellsville coal.

Apart from this, there are some piles of by-product coke that have to be liquidated, the coke being accumulated partly because it was considered injurious to let the retorts grow cold and partly because coke manufacture had to be continued to supply gas, either to municipalities or to attached steel works. The Connellsville market for spot or prompt shipment is quotable at $2.90 to $3.00 for furnace and at $4.00 to $4.50 for foundry, as for several weeks past.

POINTS IN WEEK'S MARKETING NOTES

The Exhibition seems to be responsible for an increase in business in some directions, particularly in the outfitting of exhibiting booths.

Some of the larger machine tool manufacturers have announced new prices during the last few weeks, some varying from 10 to 15 per cent.. Chain blocks are down 12½ per cent.

On a large order for machine tools there is a tendency to get away from a fixed schedule. Business is what is wanted and makers of machines are only too anxious to close the order. Small tools are still moving slowly.

A reduction in galvanized sheets is announced this week, the amount being about $8 per ton. Tubes are moving very well and metal lath is selling pretty fast.

The scrap situation is still in bad shape. Nobody seems to want to buy, and dealers have no room to put in further stocks. At present there is no sign of any quick recovery.

Pig iron has stiffened somewhat in price, especially in Pittsburgh. The demand for coke is looking up as here and there a new furnace is being blown in.

An increase in buying is looked for next month although the amount of extra business looked for is not sensational.

The tendency of some manufacturers to demand an allowance for their old equipment when buying new machines is causing some concern among dealers. One dealer claims he is handling second-hand tools for the first time in his experience.

P. E. Thring, formerly manager of Canadian Fairbanks Supply Dept., has been appointed sales manager by the Bond Engineering Works, Toronto, who are manufacturers of power transmission specialties.

* * *

Mr. Carter of the Carter Welding Co., Toronto, is in Chicago at present visiting the firm of Bastien & Blessing. The latter concern make the line of "Rigo" torches, etc., which Mr. Carter's Co. handles in Canada.

Extending Machine Shop. — The Springer Lock Co., of Belleville, are making an addition to their premises. The new quarters will be used for a machine shop, the building being 49 x 87 and two storeys high. Just now the firm is completing the installation of a large automatic press. Operations are being carried on at full speed, and so far there has been no lost time at this plant.

BETTER BUSINESS REPORTED IN TORONTO

TORONTO—Although not claiming that they are experiencing anything in the nature of a permanent revival in business, there are firms in the iron, steel and machine tool market that report better business than they have been experiencing for some months past. The coming of the Toronto Exhibition may have something to do with this state of affairs, for some of the firms pick up a lot of business out of that event, particularly in the outfitting of exhibits and putting up temporary alterations and additions.

Machine tool dealers are not getting much business, but a number of them report that their list of prospects is improving, and some of them are moving in the right direction.

There seems to be an increasing tendency on the part of many of the buyers to insist on the dealer taking some old equipment in part payment for new machinery. One dealer speaking of this tendency remarked to this paper: "It is a long time since we have had much experience in this line, and we prefer to do nothing but sell new tools. In a market such as we are going through just now it is almost necessary to depart from hard and fast rules, and do something to get the buyer into the market. It's an easy matter to get your warehouse filled up with old material in this way, and a person has to move carefully." There are some very fair orders in the market for equipment for the new technical school in Toronto.

Some of the larger makers of machine tools have announced new prices in the last few weeks, some of them varying from ten to fifteen per cent. In several cases the second, and sometimes the third reduction has been made from the prices that were prevailing at the close of the war. An estimate would place the reduction at between thirty and forty per cent. from the peak prices.

Schedules Not Adamant

"There is one thing that will tempt most of them just now," remarked one Toronto dealer," and that is a good-sized order. We had an enquiry not very long ago that would have run into a nice battery of machines of a certain type. We put the matter up to the makers, stating that we were particularly anxious to secure this business. The result was that we got a figure that was 25 and 15 off. Buyers should remember that they can buy to pretty fair advantage right now, and get all sorts of service along with their purchase."

A reduction of 12½ per cent. is also announced in chain blocks.

Small tools are moving slowly. Dealers claim that orders are costing them more to handle on account of their smallness. Renewed efforts are being made by makers and dealers alike to "dig up" anything that looks like an order, and a number of new men have been put on the road with this end in view. Prices remain the same, although

some of the larger buyers are getting pretty fair discounts that the average order does not carry with it.

Steel Market Brighter

The steel market has made a good month out of August—in fact it is one of the best months that has been experienced for quite a while. One firm stated that their business for the month would be at least twice that of any other month this year, and that they would have some money to the good out of the trading they had done during August.

A reduction in galvanized sheets is announced this week, amounting to $8 per ton. Sheets of all kinds are moving out very well, most of the activity of the steel market centreing around these and bar mill material. Dealers are still buying very closely, and none of them seem to be ready to put material in for stock yet. They are still able to secure excellent delivery direct from the mills to their customers, and as long as the mills are in shape to do this the dealer is not apt to stock up, and take the added risk of a fluctuating market.

Tubes have been moving more freely during the week, and no doubt some of this movement can be attributed to the lower price schedule which was announced a few days ago. It is expected that tube business will be better this fall than for some time past. Stocks generally are fairly heavy in tubes, and most of the orders are being filled direct from these. There is an anxiety on the part of a good many of the warehouses to get cleared out of tubes before the market gets below the point where they can get their money out. Bars for building purposes and metal lath are reported as being a very fair sale now, indicating that considerable building is under way now.

The Scrap Business.

The scrap metal dealers are neither buying nor selling. There is some little business to be had, but the big accounts that move stuff out in a hurry are not to be had. One of the steel companies opened up a couple more open hearths during the week, but their yard is full hand to last them for a good many of scrap and they have enough on months to come. There are some small accounts that might be secured now, but the average dealer prefers to do business with known firms, especially this season.

A look through one of the largest scrap warehouses in Canada reveals the fact that the place is packed with almost every line of material that with almost every line of material that could well come within the scope of the scrap metal trade. This firm at the beginning of the year wrote off a clean half million depreciation, and they are none too sure that they are out of the bush yet on this point. Every conceivable line is represented in the million of dollars worth of material that is stored under the roof. It would be possible, if the firm wished, to go out and buy more material now at greatly reduced prices, as compared to those paid some time ago, but there is no place left to store the material, and the absence of any market standards makes buyers very careful of any moves they may be considering. Scrap dealers are none too hopeful for the immediate future, claiming that signs are against any quick recovery.

MONTREAL MARKET IS BETTER RAILWAYS HAVE INCREASE IN FREIGHT

MONTREAL, Sept. 1st.—The volume of business moving generally this week is rather small, but at the same time is a distinct improvement over any one week's business for the last few months. Activity along the harbor front is very marked as there is a large amount of outbound freight, principally grain. Railways report an increase in the movement of freight. Many business men feel that this week is only the beginning of a gradual improvement in all lines of business. Conditions generally are however, too unsettled to permit of any but a gradual improvement, if the improvement is to be permanent. No very large purchases are reported but there seems to be a sufficient amount of business in small lots, to enable many plants to keep operating.

The Canadian Car and Foundry Co. are handling a number of small orders which enables them to employ a fair number of men. The Atlas Construction Co. are commencing work immediately on a new low level pumping station and expect to employ local labor as far as possible. The Molson Breweries are erecting a new 200-ft. smokestack and are rearranging steam boilers. There are many such jobs in progress which in the aggregate provide employment for a large number.

Building Improving

Building seems to be reviving a little from its "siesta" of the last few years. Probably the largest jobs in Montreal and vicinity are the new Low Level Pumping Station at Point St. Charles, which is to cost nearly $500,000.00, and the Canada Cement Co. Bldg., the latter requiring over 900 tons of structure steel.

One firm reports orders on the books of 90,000 tons of rails for the National Railways and C.P.R.

Bar stock is moving slowly, very little British steel being imported. Price of steel is hardly stable yet. Most firms prefer to quote on all work. Base price of steel varies from 3c to 3½c. There is very little call for steel sheets. On the whole business is satisfactory. Steel being produced at present yields a \profit at prevailing prices, but old stocks produced before the present levels of labor and material are being disposed of at a loss.

Machine Tools

Generally speaking the trade is very dull. Some small orders from the smaller firms are coming through. Remanufactured and second hand tools are moving slowly. There is a small but steady demand for small tools and supplies. Dealers and manufacturers prefer to quote on all orders rather than give general price lists.

Present prices are in some instances below pre-war prices, yet even this does not stimulate business. Some weeks ago dealers, jobbers and manufacturers thought the bottom price level had been reached and buying improved. However, still further reductions have occurred and many have lost faith in the market. Very little copper is ever consumed. It always seems to reappear as scrap and the result, under present conditions, is that little or no copper is being mined or refined. All business along these lines is being done on the hand to mouth method.

Pig Iron

Foundries seem to be coming into the market again. One firm reports more pig iron sold this week than they have sold for any one month in the last ten. Even this however, does not indicate anything like a really capacity business. Prices have risen slightly, in the last few days. On the whole there is a marked improvement in all lines of business and there is every reason to believe this gradual improvement will continue.

BETTER REPORTS NOW IN WELLAND

Several Industries There Expect to Resume Normal Operations In Very Near Future.

Welland.—Industries are picking up here lately. Next week the Page-Hersey Co., which has been for some months running five days a week, will return to the six-day week. A M. Mosley, general manager, says the appreciable advance in orders has warranted taking this step. He thinks it will not be long till his firm is running a double shift.

Last week the Empire Cotton Mills put on a night staff, mainly owing to the efforts of J. D. Payne, general manager, who has succeeded in securing large orders.

The Standard Steel Construction Co., which has a plant at Port Robinson, has resumed full-time operation, and there is an indication of general revival in business which will exceed that of pre-war times.

According to an Australian dispatch, the states of Victoria and New South Wales, Australia, are each sending a deputation of four railway officials to North America to study railway operation.

PERSONAL AND TRADE NOTES

THE BELGIAN MACHINE TOOL MARKET
GERMAN COMPETITION IS VERY KEEN

Belgium may be a country with a ghly developed iron and steel industry, ıt according to Samuel H. Cross, who Acting Commercial Attache at Brus- ls, Belgium manufacturers do not pro- ıce a large variety of machinery.

Speaking on the subject of the Bel- an Machine Tool Market in "Commerce eports," Mr. Cross says that the best ıown branch of Belgian Mechanical nstruction is locomotive and engine ıilding, which centers in the Hainaut ction, Ghent and Liege. Beside stan- rd and narrow-gage railway locomo- es, the industry produces steam tur- nes, gas and oil engines for marine l industrial purposes, compound mar- e engines, and horizontal engines for er craft. Gas engines are generally ed in Belgian metallurgical plants and oduce in some cases as high as 8,000 rsepower. Diesel motors are also con- ucted at Ghent, and are admitted to mpare favorably with similar engines German construction. Belgian steam gines and locomotives are well known their relatively low coal consump- n. Since the armistice, however, owing the lessened repair and construction ilities of Belgian locomotive s Belgian State railways ordered lo- motives both in the United States and England. The American locomotives ve now been delivered (150 in num-), and are, according to official state- nts by government engineers, render- superior service.

Electrical construction, though a field more recent development, is repre- ted by large plants at Charleroi, ent, and Antwerp, turning out dyna- s, motors, transformers, storage bat- es, switch-boards, telephone appara- , cables, and a varied line of access- s. American capital is considerably erested in this branch of Belgian in- try, which employs approximately 8,- workmen.

Machine Tool Production

There are only four important Belgian nts manufacturing machine tools, t located in Brussels, and one each at Lge and Bruges, producing a relative- ly imited variety of implements. One of t Brussels plants specializes on lathes o 14 to 40-in. dimensions, while the o er, which is now increasing its instal- ons to a capacity of from 1,000 to 1,- 2 machines a year, builds lathes, shap- e and pneumatic hammers of good quality. The Bruges plant, aside from re- erating machinery, turns out sev- eral models of boring mills which are considered equal to any similar makes produced outside the United States.

The principal exports for Belgian machine tools are France, England and Italy. Belgian toolmakers have frequent- ly imitated American machines, and one case is noted where an imitation of a small American drilling machine sells for 650 francs, in comparison with 1,200 francs asked for the original. The prices for Belgian tools run in general from one-third to one-half of those charged for their American equivalents. For in- stance, a plant at Liege turns out a wheel lathe selling for one-third the price of a well-known American make. On the other hand. its weight is only one-third of that of the American mach- ine, and it may be reasonably supposed that its comparative durability is in pro- portion.

There is also one fairly large Belgian plant producing woodworking machin- ery, mostly of lighter sorts in compar- ison with the products of Swedish manu- facture. This factory which has an an- nual turnover of 15,000,000 francs, re- latively large for a Belgian enterprise of this nature, is reported practically to control the French market for machines of this type.

Competition Exists

Local machine tool dealers state that before the war 70 per cent of all mach- ine tools imported into this country were of German origin. For reconstruction purposes after the armistice, however, American machine tools of all classes from the smallest millers to the heavi- est grinding wheels and boring mills, were sold in Belgium in large numbers. The War Department alone disposed of $3,500,000 worth of tools through the co- operative known as the Construction Métallique, and it is estimated that fully as large a sum was spent on machines purchased privately. Though these lar sales created a temporary advantage, this preferential position was rapidly lost as soon as German machines, at re- latively low prices. re-entered the field. While it is generally recognized by Bel- gian machine tool users that German products are not of the same high qual- ity (lathe beds, in particular, being made of inferior metal), local enterprises are now making stop-gap purchases of Ger- man tools to hold them over until a fall in the dollar makes it possible to acquire American tools at what they consider a more reasonable price.

Several agents for American machine tools who carried large stocks suffered severe losses during the latter part of 1920 owing to the readier sale of German products. One such agent at least has taken an agency for German mach- ines. The sale of American tools must obviously suffer from this practice if it spreads further. The sale of German machine tools, except in this instance, is in the hands of relatively small and unimportant commission business whose sharp methods and price cutting render matters dificult for the more reputable agents. While German manufacturers have been demanding cash with order they rarely insist on this condition when a sale depends on concessions.

The shop and factory supply business, so far as American products are con- cerned, is now more profitable than the machine tool field. American wheels and small tools of most sorts sell with relative ease, but the market is prac- tically closed to American twist drills. Not only do English twist drills offer some active competition, but prohibitive offers from Germans are beginning to appear. While there are in Belgium numerous small shops producing brass valves, the native product is not able to compete with the standardized American article.

German competition is particularly active in measuring tools and on small carbon steel articles. In the latter branch German manufacturers undersell Ameri- can products in the local market by over 80 per cent. A 36-millimeter carbon drill is being offered in Brussels for 6.25 francs in comparison with 35.15 francs asked for a well-known American drill of the same size. It is the local practice to use carbon steel up to one- half inch diameters and above that di- mension to employ high-speed steel. Ger- man price offers on micrometers are almost as exclusive as on drills. A Ger- men product, not of extremely high finish but of entirely accurate construc- tion, is sold in Brussels for 31.20 francs while the price for the corresponding American micrometer is 96 francs.

German tools of this sort placed on the local market bear no device or mark in- dicating their Teutonic origin, and even for an order of one such micrometer, the German manufacturer will stamp on it the name and address of the local pur- chaser free of charge.

QUEBEC MAKES RAPID PROGRESS

Manufacturing Activities Increase Short History of Different Trades Wide Range of Manufacture

The output of Quebec's manufacture in 1919-1920 was $890,420,023 compared with $158,287,994 in 1900. This shows quite a growth in twenty years. Some interesting data regarding Quebec's activities are contained in a recent issue of "Agricultural and Industrial Progress in Canada," and following are a few of the items which will no doubt interest our readers.

The foundation of the textile industry was laid around the seventeenth century, while hat and shoe factories were established in Quebec prior to the year 1668, and the records of 1681 show the existence at that time of four weavers of cloth, one of carpets, one ribbon weaver, four ropemakers, six hatters and one carder. The first timber manufactured in Canada was shipped from Quebec province.

Mining for ore commenced upon the banks of the St. Maurice River in 1733 and by 1737, smelting operations had been entered upon on a large scale. The first sugar refinery was established in Montreal in 1854 and the first flour mill in 1860. In 1851 the province boasted 541 grist mills, 1065 sawmills, 193 carding machines, 18 woollen mills, 13 breweries, 7 distilleries, 12 shipyards, 38 foundries, 204 tanneries, and 123 industrial establishments.

Quebec's forests are responsible for the greatest amount of industrial activity. Pulp and paper is the leading industry which in the past has witnessed a phenomenal development and is still undergoing a steady expansion. Pulp products increased in value from $2,421,068 in 1900 to $33,637,775 in 1920, and paper from $2,021,592 to $41,601,790 in the same period. Forest products employ 20,000 men and have a production value of $40,761,730, having jumped to this figure from $18,609,716 in 1900.

In the value of manufactured cottons, Quebec leads the Dominion with twelve textile plants having a capital of $37,962,311 out of a total for the Dominion invested in this industry of $58,732,941. These plants produced in 1919 goods to the value of $57,530,438 out of a total for Canada of $82,642,949. Quebec operates 83 of the 147 factories in Canada employed in the manufacture of men's clothing and they represent a capital of $14,180989 out of a total investment in the industry of $25,703,795.

Wide Range of Manufacture

Twenty plants for the manufacture of agricultural implements have the sum of $3,892,851 invested in them. Two of the eight sugar refineries in Canada are in Quebec having an investment of $5,869,592. There are 71 hat, cap and fur manufactories with a capital investment of $7,585,382 and twelve woollen textile mills with a capital of $3,126,141. A total of $3,315,328 is invested in 18 glove and mitt factories.

A very prominent Quebec industry is the manufacture of boots and shoes and out of a total production of $69,319,128 in the Dominion, Quebec is responsible for $41,689,124 from 91 establishments capitalized at $24,894,251.

Though there are nearly 500 mills for the manufacture of flour in the province these are mainly of small capacity with about twelve and a half million dollars invested. About ten million dollars is invested in 15 abattoirs and meat packing establishments. Men's furnishings are responsible for 31 factories and shipbuilding for nine yards.

The principal industrial centres of the province are Montreal, Quebec, Sherbrooke, Three Rivers, Hull and Lachine, which have in the main been responsible for the remarkable progress which in the past ten years have elevated production figures from $158,287,994 to $890,420,023. Industry is said to have become a serious rival to agriculture in the province but the two are amicable competit is progressing hand in hand and mutually aiding. Quebec has now attained the position where she can not only provide most home needs but engage extensively in the export of these products.

UPWARD TREND IS IN EVIDENCE

Business in United States Improving According to Various Sources. Further Improvement Looked For

"The changes in wholesale prices or prices of raw materials are no longer marked by sharp fluctations." There is increasing evidence, continues a writer in "New York Commercial," that one after another of the industries are settling down to a definite price basis.

Surplus stocks are moving into consumption, while the most hopeful feature of the situation is that new business is being developed on a sufficient scale in some lines to warrant restoration of capacity production. Frozen loans are being thawed out, and the banking situation is steadily improving. In the Middle West, in particular, unemployment is decreasing and while there has been a momentary let-down with some automobile factories, in general the motor trades have improved, as have textiles, rubber goods, shoes and leather. Car loadings are increasing and there has been a definite improvement in railroad earnings.

The "Annalist" also feels sure that things are on the upward trend for they say that the outlook as to business and banking conditions, both in the United States and elsewhere, present less complexity than for sometime. In their opinion however, the recovery of business is probably not measuring up to the standard which was hoped for and expected by many earlier in the year. ill progress is being made and while it ill undoubtedly be a long time before t re is any degree of prosperity akin to at which prevailed before deflation b an to make itself manifest, it seems n r- theless true that a stabilization ill come and that manufacturing will o- ceed on a larger scale because of ret n- ing confidence on the part of those o not so many weeks ago were a bit u- icky as to the trend of events.

The building revival, according to Guaranty Trust Co., of New Yor the most encouraging factor as reg ds the prospective betterment of the m- ployment situation. The importanc of this revival, in their opinion, lies in he fact that, in addition to affording m- ployment to thousands of men in he building and allied trades, it stimu es many other industries, such as s l, brick, cement, lumber, and score of others, and, consequently, increases he volume of freight for the railroads Al of this will augment the purchasing w er of the country and create a gr er demand for all kinds of commod es Still further readjustment in the p es of materials and cost of labor mus e- cur, however, before there can be a l ge building boom.

NEW SOCIETY FORMED

According to trade commissione T. O. Klath, at Copenhagen, Denmark a association called "The Anglo-D Technical Society," has been form Copenhagen, Denmark with the o of promoting co-operation between mark and Great Britain along indus and commercial lines. Capt. H. E the newly appointed representative Federation of British Industries in mark, and vice-president of the D Cable Manufacturing Co., has bee lected president of the association Sir Martin Abrahamson, a well k engineer and commercial man, has made vice-president. Ewald made following statement to the Copenh press with regard to the plans and pose of the organization:

The society which has just been f ed is to be considered in the natu a technical club. New members wi admitted only if approved by the o al members. We expect to establis timate relations with English indu and other associations, so that the k ledge and experience gained in Britain concerning various comm and technical conditions will be available to our Danish members made use of to their advantage. It i intention of the society to have mo meetings when addresses will be ma technical subjects, and it is also pl to issue and distribute various pu tions.

The recent marking regulation applied to packages and boxes pa through the customs office, will n enforced until Dec. 31 1921. This give manufacturers a chance to pr for the new ruling.

Trade Gossip

Various societies are about to hold conventions. The American Society for steel treating are going to meet at Indianapolis, during the week of Sept. 19 to 24 inclusive, while the National Safety Council are holding their annual congress at Boston during the week of Sept. 26.

* * *

The American Society of Mechanical Engineers; the Society of Automotive Engineers, and the Army Ordnance, are going to hold a joint meeting at Aberdeen, Md. on Oct. 7.

* * *

The National Machine Tool Builders Association are going to hold their annual fall meeting at the Hotel Astor, New York, on Oct. 18, 19, and 20.

Improved labor conditions have enabled considerable progress to be made in hydro-electric construction throughout Italy. Should expectations be realised in respect of all projects arranged for, at the end of 1923 there should be a further 1,000,000 horse power available for power and lighting purposes. Not the least remarkable feature of the electric industrial position in Italy is the almost complete elimination of German interests. Before the war, by far the largest amount of electrical goods came from Germany, while the control exercised through the banks was sufficient largely to exclude both French and British participation. It is proposed that hereafter Italy shall produce almost the whole of her own requirements in electrical material, and there is a strong movement towards patronising home only.

* * *

The Brantford Navigation Co., has been in corporporated under the Dominion Companies Act with 500 shares of no nominal or par value, provided it shall carry on business with a capital of $2,500, and have its head office in Montreal. The business of shipbuilder, shipagent, forwarder, carrier by land and water, etc., will be carried on.

* * *

The Belleville Motors, Co., has been incorporated with a capital stock of $40,000. It is the intention of this firm to manufacture and deal in automobiles, etc.

* * *

The International Harvester Co., at Chatham Ont., is said to be considering the making of motor trucks. At present plans are being perfected and a large addition to the plant will perhaps be erected shortly.

* * *

The Bailey Meter Co., Cleveland, Ohio are taking space at the Seventh National Chemical Exposition in New York during the week of September 12th, to be held in the 8th Coast Artillery Armoury, where they will be glad to see their friends who may be in the city that week.

The Smithville Metal Industries has been incorporated to carry on business as iron founders and to manufacture machinery, tools, implements, castings, forgings, etc. The capital stock is placed at $200,000.

The following companies have been incorporated, each with capital stock of $40,000. The Simplex Iron & Tool Co., Toronto; The Steam Valve Co., Toronto, and the Mathewson Brick & Tile Co., amilton.

The Dominion Oxygen Co., Toronto, are erecting a building at Montreal for an oxygen plant. It will be practically a duplicate of the one at Toronto, so that the addition will double the company's present capacity.

* * *

The recently organized firm of Gorman's Ltd., with head offices in Edmonton, Alta., have taken over the old firm of Gorman, Clancey & Grindley, Ltd. The new company will operate in the four western provinces and will require the use of a considerable portion of the authorized capital of $250,000, as considerable improvements to the old organization are being planned.

* * *

Rich coal deposits have been found in the Guadalquivir River Valley, according to the Semana Financiera, and the exploitation of the beds has been begun. It is said that this is likely to prove another valuable coal district to be added to those of the Asturias, Leon and Ciudad Real.

* * *

Steel work for a carbonizing plant at Victoria, B. C., for the Victoria Gas Co., is progressing favorably. The cost when completed will be around $125,000.

* * *

A new association was formed recently in Montreal, this to be known as "The Association of Building Industries for the province of Quebec." According to Mr. Church, president of the Montreal Builders' exchange, the sole object of organizing the new association was that it might serve as an official mouthpiece for the construction interests of the whole province, so that they might be in a position to give the provincial government, and especially the departments of public works and labor, the benefit of their experience.

Following were the officers elected:—K. D. Church, Montreal, president; E. G. Brousseau, Quebec, first vice-president; Alphonse Gratton, Montreal, second vice-president; D. K. Trotter, Montreal, and J. P. Lemieux, Quebec, joint secretaries. It was decided to hold the first annual meeting of the new association in Quebec city, the date to be fixed according to the time of the opening of the Legislature.

When in Toronto for the Exhibition

The Home of Fine Tools

Aikenhead's

Show Room 17 Temperance Street

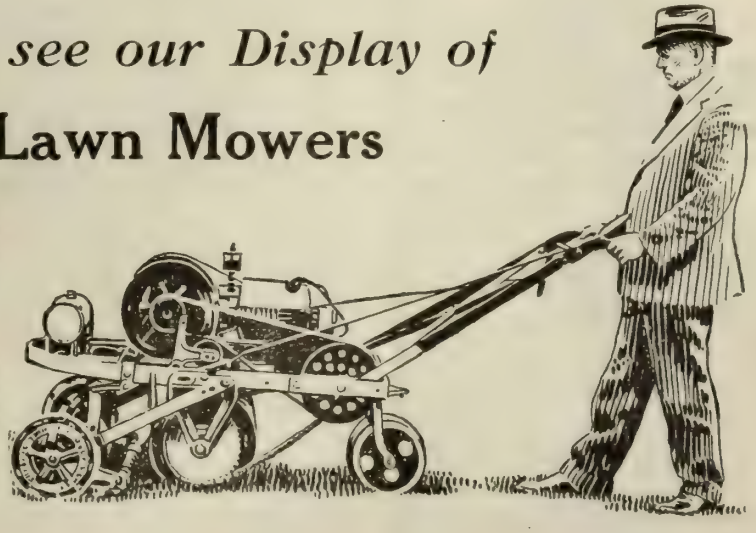
Should be your first point of call!

With the exception of our **Ideal Power Lawn Mowers** we are not exhibiting at the Exhibition this year. But the convenient location of our Show Rooms at 17 Temperance Street makes it easy for each user of up-to-date tools to see the newest advances in this line without going out of his way or without losing any time. In addition to Portable Grinders, Vises, Pipe Threading Tools, Drills, Johansson Gauges, Glue Heaters and scores of others, we will be pleased to demonstrate superior features of the.

WAHLSTROM CHUCK

This Automatic Drill Chuck is a remarkable economizer of time. It is automatic and instantaneous in operation and enables the operator to make tool changes in just two seconds without stopping the spindle of the machine.

One of the many good things about this chuck is the fact that it will hold tools whether they have tangs or not. The jaw grips on the side of shank. Made in two different styles. One style holds No. 1, 2 or 3 Morse Taper Shank Drills—with or without a tang. The other style is made in three sizes, which hold all sizes of straight shank tools from ¼ to 1 inch.



At the Exhibition see our Display of

Ideal Power Lawn Mowers

are demonstrating the 22" Ideal Junior, the 30" al Tractor, and the 84" I. Tractor Triplex on the n between the Dominion Government Building the Horticultural Building, also have a display inside the west door of the Horticultural Build-

Ideal Power Lawn Mower has proved itself to the simplest and most efficient Power Mower on market. Over 100 of these machines are in use Ontario, and each and every machine has given ct satisfaction. The Ideal Power Lawn Mower, kept working, will pay for itself in six weeks pared with cutting with a hand mower.

May we not have your inquiry and quote you on ame? If unable to visit us at the Exhibition, rite for catalogue and information.

Aikenhead Hardware, Limited

17 Temperance Street, Toronto, Ont.

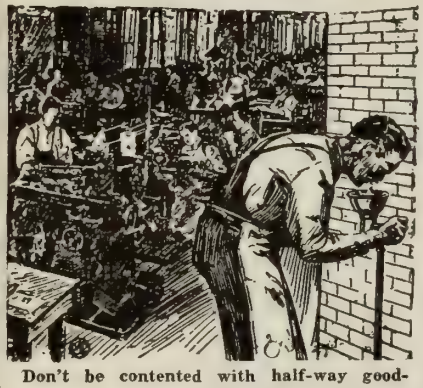
CONNECTING RODS

Continued from page 42

in a manner similar to that previously described and the holes drilled at the opposite end. The rod is now ready for fitting the boxes after which they are finish reamed for the bored holes to the proper sizes.

Machining Wrist-pin and Crank-pin Holes.

An interesting jig is used when machining the wrist-pin and crank-pin holes and is shown in Fig. 5. The rod is placed on the pads A which are made of the correct height to enable it to set parallel, as the bosses at each end have been previously machined as noted. The large screw bushing B is then tightened and as the lower end of this medium is made with a bevel or what is known as a cup bushing this coming in contact with the surface machined in Fig. 3 centers it correctly in the jig.



The small end of the element is located by means of the spring actuated by sliding vee block C, the knurled head set screw D holding it against the machining stresses. Long bushings are provided for each hole which is drilled and afterwards reamed in order to obtain both accurate and smooth surfaces. It will be observed that the jig is provided with a shelf design at the places where the rod rests, and as the drill or reamer passes through the lower bushings at A the chips drop away from the locating surfaces thus preventing clogging and insuring a clean tool as the material can be easily removed by the operator even when the rod is being worked upon.

The profile on the outside of the large end of the rod is next machined and the fixture used to hold it in place is illustrated in Fig. 6. The element is located by a large stud that fits into the wrist hole machined in the previous tool shown. The open washer shown is then slid under the threaded portion of the stud, the nut A holding it in position. The set screw B is also adjusted to force the rod back against the locating stop at the rear. The nut A is then fastened and holds the element securely in its correct location. The gang of form cutters C are used for the operation of milling the surface D, and the fixture is employed in conjunction with the circular milling attachment of the machinery.

The illustration, Fig. 7, shows the fixture used when milling the contour of the bolt bosses. The forging is located by means of two pins that fit the machined holes and after the open washers have been slid over the outer surface of the rod the two studs A are tightened to hold the element securely in position. The form cutter B is fed across the bolt bosses, machining them to the desired contour. The fixture is located by means of tongues and is fastened to the machine table to obtain the correct alignment.

A new tool, a tolerance plug gauge with replaceable ends, has been added to the lines of C. E. Johansson, Inc. These tolerance plug gauges of the smaller sizes, were formerly made solid, but the new type provides for the preservation of the unworn (No-Go) end, and refitting the tool with a new Go member. A locking device is used to keep the ends from turning when gauge is in use. This type of gauge is made in sizes from ⅛ to 47-64 inch.

? Who was the Third Man?

WHEN the retirement of Sir Robert Borden as Premier of Canada was first announced, three outstanding men were considered as his possible successors. Their names were displayed prominently in every Canadian newspaper. The present Premier was of course one of the men mentioned. Sir Geo. Foster another. Who was the third man? You would remember him no doubt if his name were displayed prominently in the daily press to-day—but he has retired from the political arena, and his name is seldom mentioned.

How easily names slip from the memory when they cease to be given publicity.

There is a lesson here. If you wish your name and the name of your products to be remembered, you must give them constant publicity.

The prudent manufacturer of machine tools, power plant equipment, or industrial supplies of any kind places his name and the name of his products where they will be seen and remembered to best advantage: **in reliable technical newspapers.**

Reliable technical newspapers in Canada are those included as members of Canadian National Newspapers and Periodicals Association. Their circulation is bona-fide and their editorial practice is carefully guarded, in fact their whole policy must conform to the highest standards else they would not be eligible to membership in the association.

One Man at the Air Drill

IN the boiler shop of the Canadian plant of a great American industry the men said no staybolt tap made could be driven easily enough to require but one man at the air drill —said they'd strike before they'd obey the order to use only one man on each staybolt tap.

But the answer came back from headquarters in "The States" that the *"Maxi"* Staybolt Tap made by the GTD Corporation was different; that only one man was needed and that only one man must be used in Canada.

Headquarters even sent photographs to prove their statement but they thought the photos must be fakes, and so the Railroad Union sent a committee to see it done—and they saw and were convinced.

This is one of the best arguments we can give you on the *"Maxi"* Staybolt Tap. The saving in labor is not the only argument that there is, however.

The *"Maxi"* Staybolt Tap has the *exclusive* features of a *pilot point*, which finds the hole in the inner plate immediately, and guides the tap into it—a *chip breaker*, which prevents accumulation and wedging of chips —an extra long taper threaded section—specially designed flutes.

Consequently the *"Maxi"* cuts many more threads than any other staybolt tap on the market.

Let us tell you more about this remarkable tool. Clip the coupon and send it in. No obligation, of course.

Quick application, belt saving features, economy and general satisfaction make ALLIGATOR Steel Belt Lacing the logical belt lacing to sell your trade.

ALLIGATOR Steel Belt Lacing works equally well on any kind or thickness of power or conveyor belting. Anyone can put it on. Requires no tool but a hammer. Three minutes' average time makes a permanent, flexible joint, with two working surfaces, that is stronger than any other known.

ALLIGATOR Steel Belt Lacing is being advertised nationally to master mechanics, shop superintendents, purchasing agents, executives, etc., in all classes of publications. Demand is growing stronger. A size and type for every need. Write on letterhead for samples and trade prices.

Be Sure Your Files Cut Clean

As soon as a file ceases to cut keenly at every stroke it has outlived its usefulness.

You will actually save money by throwing it away and buying a new file, because files cost less than workmen's time.

Long, efficient service is ensured by specifying one of these brands when ordering.

MACHINERY AND SUPPLIES

Are You Taking Advantage of our "Exhibition" Invitation?

Many Toronto Exhibition Visitors will be taking advantage of the convenient location of our warehouses to "drop in" for a visit of inspection. We hope that you intend doing so also. Either at 131 Front St., W.—practically next door to the Union Station or at 27 Bathurst St. —on the way to the eastern Exhibition entrance —a cordial reception awaits you.

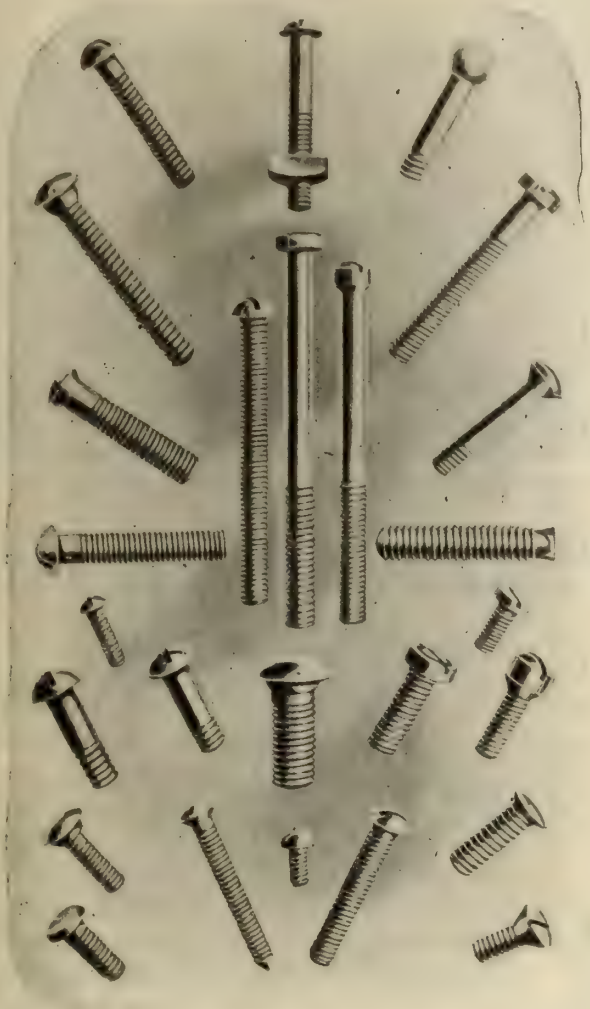
Canada's Dependable Machinery and Supply House

See Petrie before you place your orders for new equipment. Our fifty years of experience and square dealing will mean a lot to you.

If you can't call at our office or warehouse write us for particulars of any machine you need.

These and Scores of other Machines Displayed--

at our Bathurst St. warehouse. This huge structure covers



3½ Acres of Floor Space

and will contain a varied assortment of lathes, planers, millers, grinders, shapers, drills, boring mills, punches, shears, boilers, etc. No matter what you need you'll find it there.

H. W. PETRIE Limited

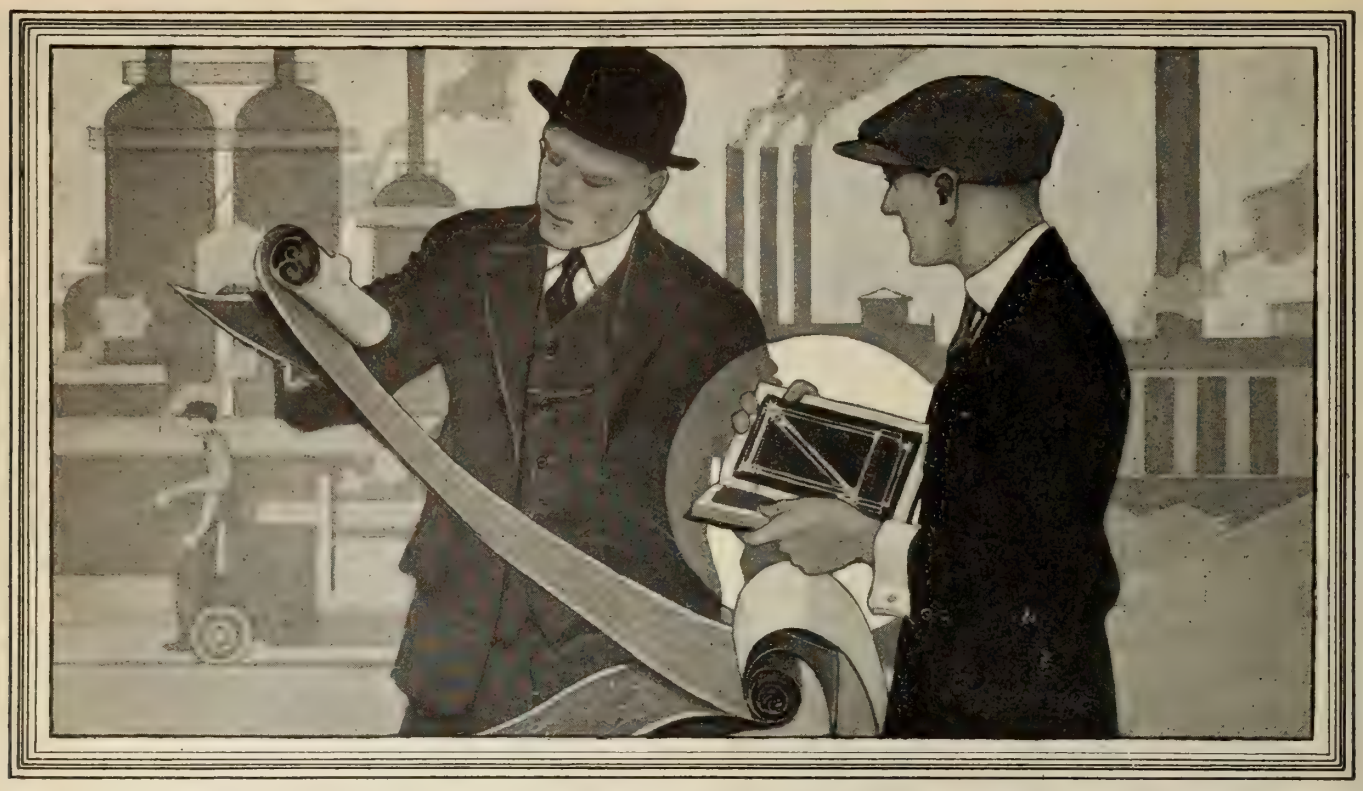
TORONTO and HAMILTON

"Repeat Orders" Built Our Business

Quality Products At a Modest Price

You can "sting" a man once but he doesn't generally "bite" the second time. If our policy was one of exorbitant initial prices we would have been out of business long ago.

But this is not our method. While we produce the highest quality Machine Screw Products possible we ask only a moderate profit. But we make our money through "repeat orders."



Canadian manufacturers recognize this. They know they get true economy by using Torrington Standard and Special Machine Screws, Rivets, Threaded Wires and Specialties.

"Why Don't You Use PHOTOSTAT Prints"

And the PHOTOSTAT makes no mistakes.

It makes photographic facsimiles.

Let us send you a booklet containing letters from many firms telling of large savings through the use of the PHOTOSTAT.

IT is not necessary to carry around large, awkward blue prints for field and shop work. PHOTOSTAT copies can be made either of the blue print or of the original drawing, in a few minutes' time, and at a convenient size so that they will fit into a loose leaf book which is easily handled. Furthermore these copies will not fade or smut and being of uniform size can be conveniently filed for future reference after the job is completed.

The installation of a PHOTOSTAT in an industrial plant means the elimination to a large extent of tracing work, because pencil sketches are copied direct in photographic facsimile; or, if the original sketch is not available the blueprint can be copied equally well. Catalog pages, advertising layouts, maps, production charts, test reports, and documents of all kinds are also copied in photographic facsimile by the PHOTOSTAT with a great saving in time and money.

The PHOTOSTAT is made by the Eastman Kodak Co., exclusively for the

LEAK INSURANCE

The Welded Tank answers ideally the demand of the industrial engineer for tanks which must be tight, strong and permanently leak-proof.
The oxy-acetylene process has made such tanks possible and

Prest-O-Lite

DISSOLVED ACETYLENE

because of its high quality and extreme portability has increased the usefulness of the welding and cutting torches a thousand fold.
Especially is this true wherever large cumbersome sections are to be welded —Prest-O-Lite can readily be carried anywhere—it goes to the job.

Tank makers are assured of the highest quality of gas and a constant and unlimited supply by using Prest-O-Lite.

A chain of plants and warehouses is kept busy meeting the demand for this most useful of gases.

PREST-O-LITE COMPANY OF CANADA, LIMITED

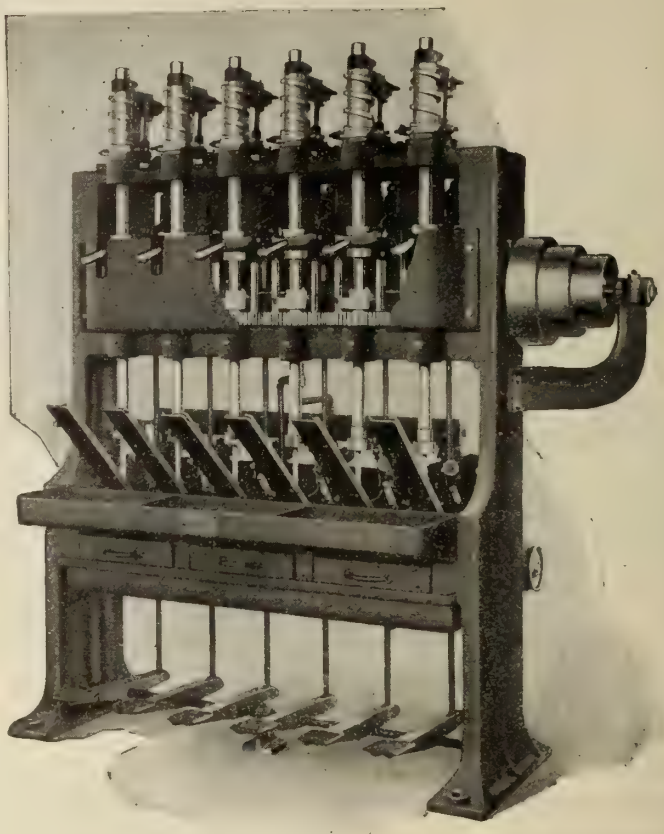
A Quick and Easy Means

of Tapping Square or Hexagon Nuts

MODERN manufacture and industrial readjustments demand a machine tool, which, besides being a high-speed producer, is capable of precision work under the most severe service.

Of such nature are Acme Nut-Tapping Machines. These easily-operated tools are limited to speed only by the endurance of the taps. For this reason Acme Machines most profitably meet to-day's demands.



One plant has been using two Acme Tappers for eight years. They have subjected them to the most strenuous service, yet to-day each averages 10,000 threaded nuts per nine hour day with a spindle speed of 100 r.p.m., the limit of tap endurance on the tough material used.

This concrete example of Acme performance is being emulated in hundreds of other shops.

If you want, then, a convenient tool, a fast and accurate tool, a tool that will stand up indefinitely—look for the name "Acme."

In every respect Acme ability clearly reflects the years of building experience.

Write for illustrated catalogue of Bolt, Nut, Rivet, Upsetting and Forging Machinery.

ACME

Nut Tapping Machines

Acme Six-Spindle, Semi-Automatic Nut Tappers have many important features which facilitate operation and increase speed. Each spindle is equipped with automatic lifting device which permits automatic feed to place nut under tap. Every action has been carefully developed and proved correct in practice. Write for further details.

D.K.McLaren's

GENUINE BRITISH-OAK TANNED

LEATHER BELTING

TRADE MARK

The cheapest form of good transmission

When estimates show that a leather belting will transmit 25% more power than the same size belt of any other material, your biggest saving lies in the use of leather belting. But what of the leather belting you choose?

Are you using one with as big a "dependable performance" record as is attatched to D.K. McLaren's Belting? For many years this belting has been the popular choice because it gives minimum stretch, minimum slippage, fewer breaks, and longer life. *D. K. McLaren's Leather Belting will hold your power loss to less than 3 per cent.*

The reason lies in two things. Choice of material and method of tanning. D. K. McLaren's Leather Belting is made exclusively from close-trimmed butts of the finest selected hides, tanned by the Genuine British Oak Method until extremely tough and pliant.

The Oak Leaf is the sign of this dependable belting. Write us for list of users.

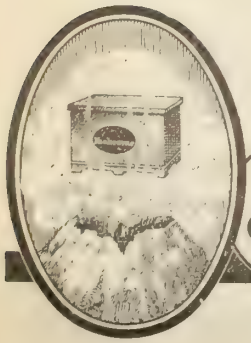
THE NATIONAL ACME COMPANY

MONTREAL, P. Q.

DE COURCELLES G. T. R. R.

The Mettle of the Cutting Tool



BASIC steel of proper quality may be the beginning of a good tool but it is far from the finished tool that meets the demand of present day practice.

And so it is with heat-treating equipment. The most highly perfected furnace equipment and other materials are handicapped if containers, muffles, racks, etc., crack, warp, scale and change in other ways that interfere with the process.

Cast Nichrome has not only contributed to surer results but it is a mighty factor in heat treating economy. Thousands of hours at 1800 deg. F.—without warping, cracking, scaling, etc.—are guaranteed. Shorter heats and less fuel consumption are inevitable.

Machining Delco Generator Frames

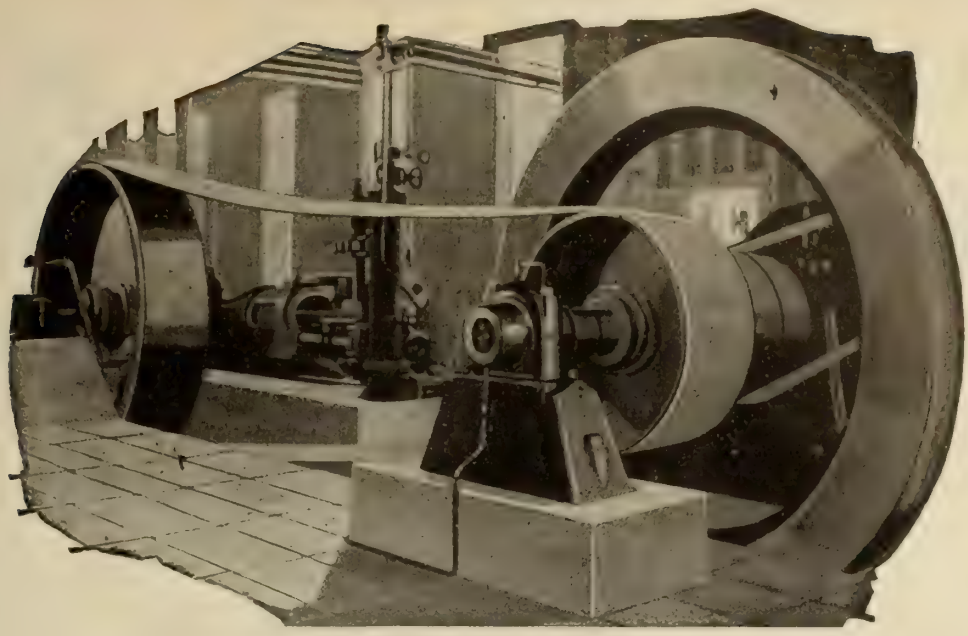
The photograph above shows a tool set-up on a Steinle 24-in. Turret Lathe for turning out Delco Generator Frames at the plant of the Delco Light Company of Dayton, Ohio.

The chucking fixture revolves in a steady rest and is equipped with centering and stop pins for centering and locating rear end of frame by pulling sleeve collar forward. Set screws hold the front end in place. The turret fixture is reinforced in the machining operation by the overhead bar support; thus preventing undue chatter or jar under the heavy cuts taken.

This is only one of a number of installations in plants manufacturing electrical equipment where the Steinle is called upon to produce various parts from castings, forgings or bar stock.

In view of present manufacturing conditions it is invariably performance that counts and the Steinle qualities of accuracy, speed, ease of operation, power, reliability, and economy of upkeep are guarantees of satisfactory performance on your own work.

Material—Cast Steel
Finish—Bore, Counterbore, Face Bottom, Face Lugs
Time—25 Minutes Each



Why not send us your blueprints if your requirements call for the installation of equipment of this character? We shall be glad to furnish you with production and tooling estimates, or to have a qualified representative call and take up the question of Steinle methods as applied to your production problems.

The Acid Test
of the business publication

Turning the spotlight of publicity upon quality and quantity of circulation.

EVERY buyer of advertising space in any publication should be fully acquainted with all facts and figures concerning circulation. He should know exactly how many copies are printed of the medium he is giving his consideration; he should know how many copies are actually mailed; how many copies are being paid for, and to whom they are going. By this information only can he intelligently judge if his money is being soundly invested.

"But how can I secure these facts and figures?" he may well ask, "and can I rely on the information provided?"

If the publication under consideration is a member of the **Audit Bureau of Circulations** he can rest assured of securing complete and authentic information. The high standing of the Audit Bureau of Circulations is universally acknowledged; it includes among its members the leading publications of America, and its audits are thorough and unquestioned.

A worthy sister to the A. B. C. is found in the Canadian National Newspapers and Periodicals Association, doing like work in the interest of both publisher and advertiser but covering a broader field of endeavor. This association not only furnishes data to advertisers—it assists its members to become better papers to read and better papers in which manufacturers can give publicity to their products.

It is interesting to note that the four technical newspapers of the MacLean Publishing Co. hold membership certificates in both the **A. B. C.** and **C. N. N. & P. A.** These papers include Canadian Machinery, Power House, Canadian Foundryman and Marine Engineering—papers which are unafraid to submit to the acid test of the quantity and quality of their circulation.

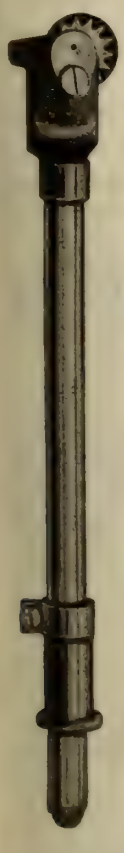
Quantity Production of Shafts in Automatic Heat Treatment Furnace.

PRODUCTION MANAGERS

The following advantages are secured by the Continuous Method of Heat-Treatment :

Increased production per unit of floor space.
Reduction in manual labor per unit of production.
Uniformity of product, resulting in decreased scrap, following less dependence upon the human element.
The fuel economy that naturally follows the direct transfer of heat in spent gases to incoming material.
Improvement in working conditions by cooler shop.



In short, the saving in cost of the finished product due to economy in labor, time, fuel, floor space, decreased rejections, etc.

Do these advantages appeal to YOU?

Write for Bulletin 217-T and learn whether this method is adapted to your product and manufacturing conditions.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

HENDEY

The name Hendey on a lathe, shaper, miller or centering machine has come to be recognized as a mark indicative of exceptional performance. To make sure that every machine will live up to the Hendey reputation, each is subjected to a careful, well-rounded system of tests before it is passed for shipment.

The test here shown is for the alignment of the tai. spindle with head spindle of a Hendey Lathe. The requirements allow the axis of the tail spindle to be either exact with that of the head spindle or else run not to exceed .001" high. The latter is not objectionable as in cases where tailstock is frequently moved along bed, the first wear will tend to bring the tail centre in closer alignment with the head centre. A record showing results of each test on machine is furnished the purchaser.

Malleable and Cast Iron PIPE FITTINGS

Made in Canada and Exported Abroad

A LARGE plant, up-to-date facilities and thoroughly experienced staff place us in a position to offer unequalled quality, price and quick delivery on Malleable and Cast Iron Pipe Fittings; both screwed or flanged, black or galvanized. All sizes from ⅛ inch up.

We make a specialty of exporting our products and can furnish designs required in any country, such as the Whitworth or "V" thread in use in England, the Metric Pitch in France, or the W. S. Standard in use in Canada and United States.

We will be glad to answer your enquiries.

Jacobs Super Chuck

Patented 1909-1915. Other patents pending

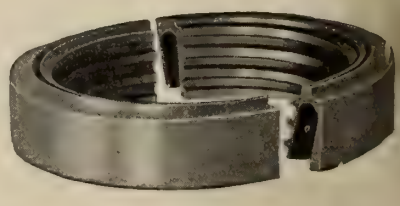
A Look Inside

Here are the several parts—carefully designed, exactly fitted, perfectly made—that guarantee the Jacobs Super Chuck to hold a drill tight, to hold it right, and to keep on doing its work indefinitely.

FIRST THE BODY—scientifically casehardened; size limits within .0005″, arbor hole ground on a special fixture with six gages to position it accurately in relation to the hole for the jaw.

THE SLOT FOR THE NUT, correctly located in relation to the jaw holes by means of micrometer gages, insures a properly fitting thread on the nut and jaws.

NO WEAR ON KEY HOLES because of the deeply casehardened body, result—a well fitting Gear on Sleeve and Key.



THE JAW, OF TOOL STEEL, has glass hard gripping surface; threads are tough, and all surfaces are ground on centers to within **a quarter of a thousandth** of an inch.
THE NUT, of special analysis steel, is ground after heat-treatment, in correct alignment with thread; tolerance .0005″.

THE BALL RACE comes within limits of .0001″; finest grade balls are used. An important point is the pitch of thread on nut—angle is 90 degrees to center line of jaw, so part cannot run over thread of latter.

The Jacobs Super Chuck centers a drill, **accurately,** and will continue to do so after years of use. It saves its cost time and again by preventing drill breakage. Its correct balance preserves bearings of your drilling machine—order a Super Chuck from your dealer.

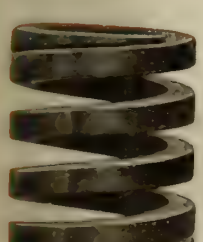
ANNOUNCEMENT

To Our Many Customers—

and friends in Canada, we take pleasure in announcing the incorporation of the Wallace Barnes Co., Ltd., in Hamilton, Ontario. This corporation, with a completely equipped factory and under the management of men of long experience, is now ready to enter into the manufacture of springs for the Canadian trade.



The quality of output and the financial integrity that has characterized the parent plant in Bristol, Conn., for over half a century will characterize the Canadian plant.

We trust we may have and merit your inquiries for our products.

The Wallace Barnes Co.,
Limited

HAMILTON — ONTARIO

STAYBOLT TAPS

The Better the Man, the More He Appreciates Them—

Not only good when new, but heat treated and seasoned to maintain this goodness. Can be ground on face of cutting edge without affecting their size. That's why you'll find Pratt and Whitney Stay Bolt Taps on the job long after cheaper, "just as good" tools are buried in the scrap pile.

Threads accurately and cleanly cut, with the least expenditure of time and effort, are other reasons why these better Taps are favorites in the shop.

If you've used them before, you know just how good they are. If you haven't, send us your first order—we know you'll be back for more. They're carried in stock in our sales rooms in all large cities.

Building for Bigger Business

DOMINION OXYGEN has won such preference everywhere in Canada that the Dominion Oxygen Company Limited is constructing another plant with all possible speed at Montreal.

This manufacturing unit will have a producing capacity again as large as that of our plant in Toronto, and will provide facilities for even quicker and better service than heretofore.

With twice the output of this uniformly pure oxygen to take care of constantly increasing demands, ample reserves will be maintained at all times at our various distributing stations to insure immediate supply for your needs — whether you require one cylinder or hundreds.

No matter where your location—at nearby industrial centers or miles away on remote and isolated jobs—forward your order to the nearest of our six plants and distributing stations and it will be filled on the day it is received.

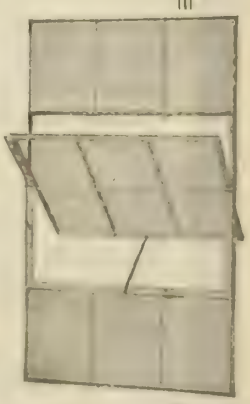
Are You Willing To Be "Shown"?



We firmly believe we have in "Boca" Solid Steel Sash, a superior sash to be used in the erection of factories, schools and all fireproof buildings—superior in model, workmanship and special features.
You as a builder or contractor won't fail to see the outstanding advantages of

BOCA SOLID STEEL SASH

(1) Its three point weathering ventilator feature.
(2) Its locked joints that assure absolute rigidity and as a result make the sash easier to erect.
(3) Absolute economy in construction—the maximum material is used, area of section being retained.

We are anxious to have you investigate "Boca".

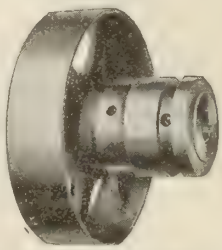
THE JOHNSON FRICTION CLUTCH



It's a Johnson Lineshaft Drive

A battery of twelve light presses, all on a bench about 30 x 5, driven from one lineshaft with Johnson Clutches controlling the machines.

Illustration by courtesy of The New Departure Manufacturing Co., showing bench presses in operation at their Elmwood Plant.

FRICTION CONTROL MEANS BETTER MACHINERY

We specialize in applying the proper type of friction clutch on any sort of an installation. Standard clutches available from stock, and special models developed to suit conditions.

COMPARE IT FOR FIRST COST

Twelve Clutches against twelve complete counter shafts, or twelve individual motors.

COMPARE IT FOR EFFICIENCY.

Quick, smooth control against the sluggish tight and loose pulley. Or one motor consuming current instead of twelve.

COMPARE IT FOR SERVICE.

You know the failing of belts—the continual attention they require, especially when they are shifted. If you don't know Johnson Clutch Service, just give it a trial.

Write for our booklet

"Clutches As Applied to Machine Building." and our Yellow Catalog.

The New Canadian-Detroit Double-D Rolled Drill

Made in Canada

PRODUCTION requirements in an ever-increasing number of plants necessitate the use of a strong, accurate drill, specially designed for hard drop forgings, steel castings, and other alloy steels equally tough and difficult to drill.

For this service we have developed a hot rolled process drill known as the Canadian-Detroit Double-D (DD) Rolled Drill. It combines the strength of the forged type drill with the accuracy and uniformity of the milled type.

The flute of the DD is formed straight from the bar stock by successive passes through specially built and patented rolls at a temperature of 1850° F. This mechanical rolling of the flutes produces a refinement and uniformity in the grain of the steel and gives additional density at the centre and at the outer edge. Each drill is rolled separately, and the rolls are so designed and operated as to produce the same uniform increase in web thickness as is obtained in high-grade drill of the milled type.

The fluted drill is reheated and twisted in a specially designed automatic machine. The twisting process is held absolutely uniform, giving the same increase in helix angle from shank to point, 27° to 32°: this standard has been adopted on our milled drills and has been proven by exhaustive experiments to be the most efficient.

The DD has increased production and cut drilling costs in many of the finest plants in Canada. A fair test will convince you.

Manufactured and carried in stock at Walkerville in all sizes from ½ inch to 1½ inches.

We also manufacture and carry in stock all sizes and types of high speed and carbon milled drills.

The Acid Test
of the business publication

Turning the spotlight of publicity upon quality and quantity of circulation.

EVERY buyer of advertising space in any publication should be fully acquainted with all facts and figures concerning circulation. He should know exactly how many copies are printed of the medium he is giving his consideration; he should know how many copies are actually mailed; how many copies are being paid for, and to whom they are going. By this information only can he intelligently judge if his money is being soundly invested.

"But how can I secure these facts and figures?" he may well ask, "and can I rely on the information provided?"

If the publication under consideration is a member of the **Audit Bureau of Circulations** he can rest assured of securing complete and authentic information. The high standing of the Audit Bureau of Circulations is universally acknowledged; it includes among its members the leading publications of America, and its audits are thorough and unquestioned.

A worthy sister to the A. B. C. is found in the Canadian National Newspapers and Periodicals Association, doing like work in the interest of both publisher and advertiser but covering a broader field of endeavor. This association not only furnishes data to advertisers—it assists its members to become better papers to read and better papers in which manufacturers can give publicity to their products.

It is interesting to note that the four technical newspapers of the MacLean Publishing Co. hold membership certificates in both the **A. B. C.** and **C. N. N. & P. A.** These papers include Canadian Machinery, Power House, Canadian Foundryman and Marine Engineering—papers which are unafraid to submit to the acid test of the quantity and quality of their circulation.

WHY WORRY ABOUT BELT PROBLEMS?

When We Can Ably Do It For You

Dunlop Belting Service is of inestimable value to Belt users who are adding to their Belting equipment.

Because it is a service that saves for the buyer—protects his interests in giving him the right kind of belt or belts needed.

We shall be glad to talk to you about your Belting requirements and also tell you the facts about

"GIBRALTAR REDSPECIAL"

(The original Red Frictioned-Surface Belt of Canada)

which have made it the most favored Belt for all manner of transmission work.

Dunlop Tire & Rubber Goods Co., Limited

Head Office and Factories: TORONTO. - Branches in the Leading Cities.

Makers of High-grade Tires, Hose and Packings for all Purposes.

Money-Saving Information

"The most useful information contained in any paper I get"—so a Western banker writes in to-day's mail, renewing his subscription for FINANCIAL POST.

"Very often," his letter goes on to say, "I am called on to suggest investments for small amounts, sometimes as low as a few hundreds, and I find your Investors' Inquiry Service a reliable partner to consult. If every investor knew there was such a service at his call it would surely lessen the losses of many of these people."

The Investors' Inquiry Service fills just that need. Unless you are perfectly sure of your investments, write us before you buy.

It costs FINANCIAL POST subscribers nothing to be sure before placing hard-earned savings in stocks that may never have a chance of paying dividends.

Trained service men will give you the benefit of keen analysis based on the facts behind the securities you are considering. This is one of many features enjoyed by our readers.

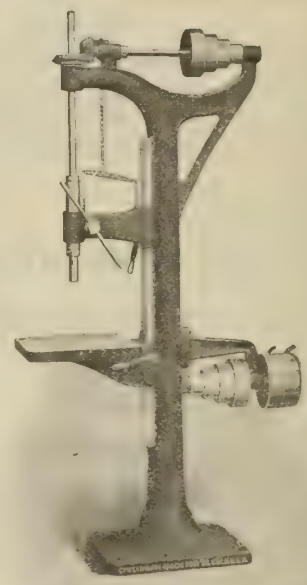
PETRIE

Is it a Drilling Machine?

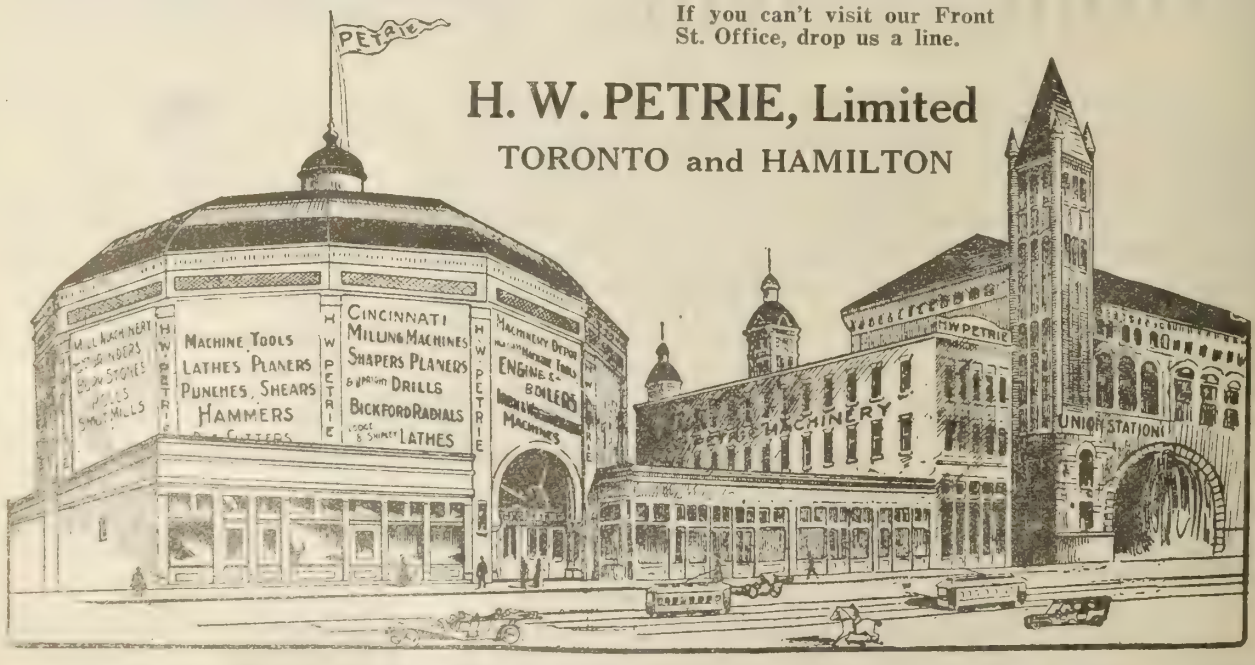


"The Cincinnati-Bickford Line Will Meet Your Requirements"

We wish there were sufficient space to go into details about the Cincinnati 20 inch High Speed Drilling Machine. However we can tell you that it is the best tool you can use for drilling holes from ⅛″ to ¾″ in diameter. Even larger holes can be drilled by using slower feeds. It is heavy and substantial and supplies abundance of power to the twist drills.

Canada's Dependable Machinery and Supply House

Let us give you complete details. If it is not Drilling Machines, there are hundreds of others in our warehouse that we will be glad to explain. The line includes Lathes, Planers, Shapers, Punches, Shears, Hammers,—in fact everything for the iron-working and wood working industries.



Cincinnati Sliding Head, High Speed 20-inch Drilling Machine.

In addition to the High Speed Drilling Machine illustrated, we can supply Heavy Pattern Upright Drilling Machines in five sizes. Also Radial Drilling Machines in Plain and Universal types.

If you can't visit our Front St. Office, drop us a line.

Good Times Just Ahead

PROSPERITY is within our reach in Canada.
All we need to have and to hold it is a sane, sure grasp on its simple elements.

They are Industry, Integrity, and Faith.

These are the cardinal virtues of human relations. They are the underpinnings of healthy, natural business life and the foundation of a wholesome social system.

They are the fountainhead from which Progress springs. A well-known business economist has called them the "Fundamentals of Prosperity."

Your purchases are an expression of Faith. They are evidence of your Industry. Make them confidently from business institutions of Integrity.

Buying is the backbone of prosperity. An active market means more employment, steadier earnings; benefits are passed around.

Wise spending gives stability to earning and for that reason is far-sighted thrift and sound economy.

The call of to-day is for cheerful thinking, willing working and constructive action by you—everybody—NOW.

To-morrow's change for the better will come about through the combined efforts of each and every one of us.

By sheer force of numbers and co-operation, by the high power of heart and mind, we can put Business on a firm, stable basis.

We can do this because all of the material factors making for better business are right.

Let us link our faith with industry, our vision with courage, and forge ahead.

Let's make an uncommon effort toward a common end—Good Times.

This extra heavy steel "C" Clamp has long hub and oversized screw made of chrome nickel alloy steel—made to stand up under the most severe conditions.

Some Precision Measuring Methods Adopted

Microscopic Measuring Machine for Testing Screw Thread Tools, Form Tools, Gauges, Etc.—How Machine is Usd—Measuring Pitch and Angle of Threads—Diameter Measuring Machines

THERE was a period when a thirty-second looked to a mechanic like a thousandth part of an inch, but these days of precision and interangeability, the craftsman actually eats a mere thousandth as an every day currence. Since the light wave method measurement came into being a millth of an inch is a commercial possibty. We will not attempt however, in present material to describe the light ve system, but shall confine our attion to two machines that are found common use through industrial nts.

ake for example Fig. 1. shows a roscopic measuring machine that is d as a convenient and accurate methof taking the measurement of screw ad tools, form tools, gauges, threaded k, and similar articles with a conThis type of machine is well a- for measuring lengths, angles pitches. It does not depend on s for its accuracy, but upon end suring rods and large-dial micros graduated to .0001-in. It can, therefore, be relied upon to give accurate results throughout its life, as the measuring rods which are used in making all length measurements can be readily checked by well-known means.

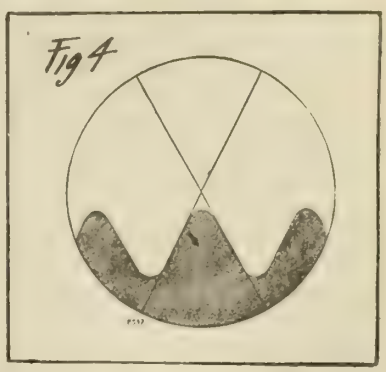

Fig. 2 — A Limit Gauge.
Fig. 4 — The two hairlines set to the profile of the thread for angular measurement.

The machine consists of two main parts viz., A. a rigid box bed, and B. a microscope. The rigid box bed carries a table capable of 12-in. movement by accurate amounts through the insertion and removal of standard hardened steel measuring rods of known length between flat pieces which are hardened; these contact pieces are mounted one on the end of the bed and one on the end of the table. This table is fitted with a pair of centres, one of which is adjustable in a crosswise direction to enable work to be lined up accurately.

The Microscope

The microscope has a vertical movement by means of rack and pinion for focussing, and is mounted on a compound slide rest, with screw movements parallel with the slides and at right angles to the table slide. It is fitted with two hair lines across its diameter, one rotating with the outside tube and the other rotating with the eyepiece.

The outer tube carries a large dial carefully graduated in half degrees. The eyepiece carries a vernier, which enables readings accurate to one minute to be made. Thus the angle between the two hair lines is indicated to the finest commercial accuracy.

A Light Projector, clearly seen in photograph, is fitted to the machine to project parallel rays of light through a lens on to a mirror placed at an angle, and so past the work. When measuring threads this attachment eliminates all shadows and light projected from the flanks of the thread which tend to make the object indistinct. The mirror is adjustable to suit the lead of the thread, and enables the object to be defined clearly through the microscope.

This type of machine is exceptionally

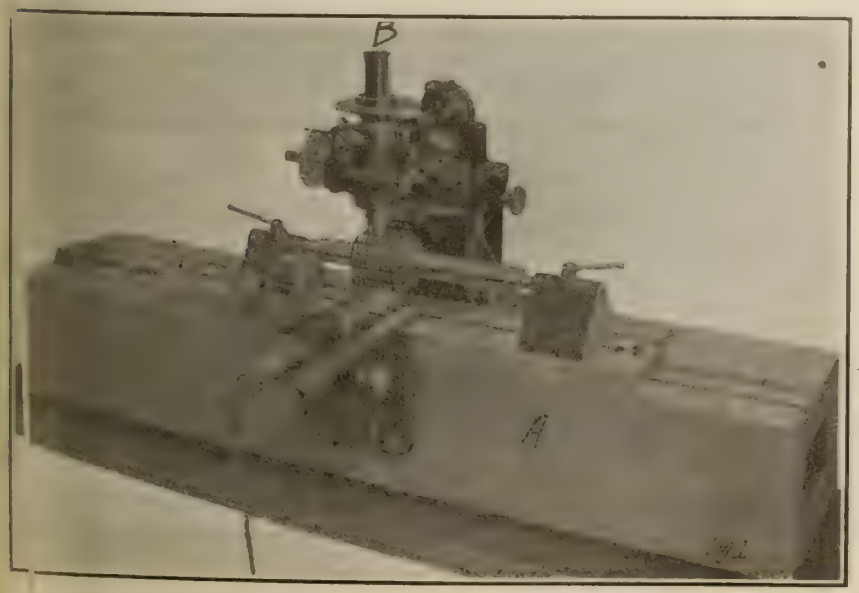

Fig. 1 — General view of Measuring Machine.

...ines of Alfred Herbert Ltd., Coventry, ... and Toronto, Canada.

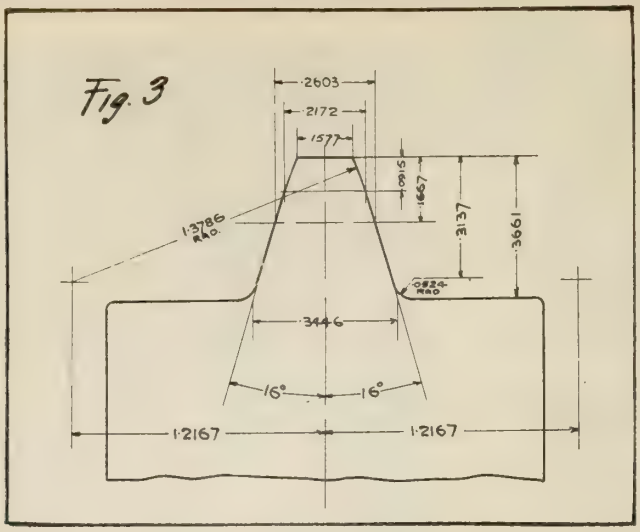

Fig. 3 — A Master Template for a Gear Hob Form Tool.

universal many classes of work being checked by its use. The following two examples of work with some observations on the modus operandi employed, will no doubt suffice to convey to the reader the principle of operation.

How Machine Is Used

In making a plain length measurement, the work is clamped on the table-it must be clamped in order to avoid any movement of the work—and the table is clamped to the bed, a measuring rod being held firmly between the two contact pieces. The microscope is then focussed on one end of the piece or part to be measured, with the hairlines covering a defined point from which the measurement will be made.

The measuring rod is next substituted by another or different length and the table is adjusted and re-clamped, with the new measuring rod firmly held. Then, by looking through the microscope, it is quickly seen whether the part to be measured corresponds with the difference between the lengths of the two measuring rods. If it varies, the compound slide can be adjusted till the hairlines cover the second point that should have come immediately under them if the part had been correct. The micrometer on the compound slide registers the error. The hairlines are very useful in making such measurements, as they can both be rotated; they can thus be set to coincide with any part or profile to be measured.

The first example to be considered will be the measurement of a simple gauge or templet, as illustrated in Fig. 2. In measuring a piece of this description, it is first necessary to select two meauring rods with a difference in length of something within 0.5-in. of the lengths to be measured; in this case the two rods should have a difference in length of 2.5-in.

Fix the longer rod between the contact, and clamp the table. Carefully set the templet with its long side parallel to the edges of the table and with the left hand end of one recess under the microscope. Set one hairline to cover the long side and the other at right angles to it, with the intersection coinciding with the outer corner of the recess. (Note.—In setting the templet with its long sides parallel to the travel of the table, advantage can be taken of the hairlines. One of these should be set parallel with the templet; then slowly move the table endwise. By adjusting the hairline and the templet with the table movement, exact parrallelism can be obtained. Carefully clamp the templet to the table and re-examine to see that parallelism has not been disturbed.)

Change the measuring rods and move and re-clamp the table; then adjust the compound slide till the hairlines cover the outer corner at the other end of the recess. In the case of the high limit side, if the templet is correct the compound slide will have to be adjusted 2.5--in. minus 2.422-in. that is, .078-in., which measurement will be registered on the micrometer.

Repeat this for the bottom of the recess, then measure the depth, setting one hairline to cover the outer edge. The compound slide can then be adjusted till the hairline covers the inner edge of the recess. It is important that one does not first forget to set the microscope to the required dimension an then try to persuade himself that the hairlines coincide correctly with the work.—First set the hairlines to the work, then take the reading.

Another Example

Fig. 3 represents a master templet, for checking form tools used in cutting gear hubs. In making such a templet it would be advisable to check the marking out on the microscopic measuring machine, as the dimensions for the radii can then be checked. After the templet is cut out, the angle of the flanks and the dimensions of the tooth thickness on the pitch line (.2603-in.), on the width (.2172-in.), and on the face (.1577-in.) can easily be measured. The depth measurements can also be made.

Threads finer than 6 per inch can have the pitch and angle measured in one operation. For coarser threads it must be done in two operations, using only one side of the thread for measuring the pitch and using the adjustments of the compound slide for measuring the angle. Focus the microscope on a thread profile near one end of the work. Rotate one hairline till it exactly coincides with one side of the thread. Repeat with the other hairline for the other side of the thread. It may be necessary to adjust the compound slide while doing this.

Note the readings on the dial of the microscope—this gives the exact angle of the thread in degrees and minutes. Next, move the table endwise a definite number of inches—any amount up to 12-in. is possible on the machine—and look through the microscope. If the hair lines exactly correspond with another thread it may generally be taken that the number of threads per inch is correct, though it may be as well to mark and count them as a precaution. If the hairlines do not correspond, adjust the microscope sideways until they do, and note the error on the micrometer.

Depth of Thread

Superimpose one hairline over the other, and adjust the work and the microscope until the hairlines just touch the crests of the threads. Next adjust the compound slide until the hairlines just touch the roots of the threads—the micrometer then registers the depth of the threads, see Figs. 4 and 5.

An intelligent operator quickly

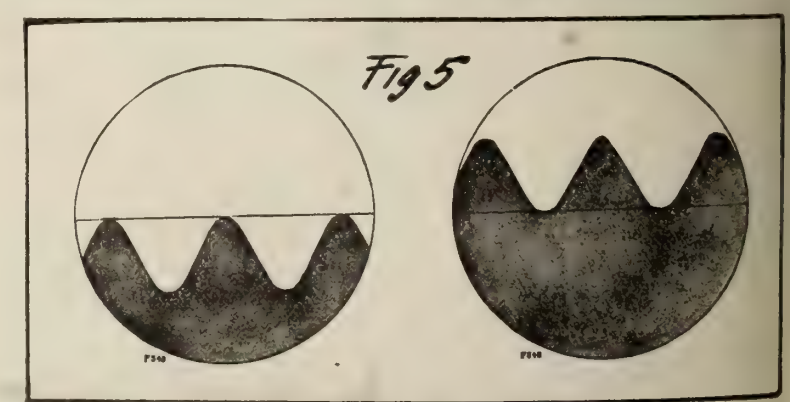

Fig. 5 — The two hairlines superimposed and set to the crests of the thread, then adjusted by the compound slide to the roots. The depth of thread is then given by the micrometer.

omes adept at rapid measuring and hecking of contours, etc., and a little ractice enables the user to undertake ork of a varied and comprehensive nge.

Diameter Measuring Machines

The production of accurate screw reads, such as are required in present y practice, has been occupying the inds of engineers for a considerable ne. The importance of obtaining satisctory results and the universal desire reach a higher standard is evidenced the repeated references on e subject appearing continually in most every technical publication. the circumstances of the case are instigated in detail it will at once beone apparent why the task of making screw, the threads of which will fit eir counterparts exactly, is by no ans an easy undertaking. The outside, ective and root diameters must be ht, likewise the radius at crest and t, and particularly the form and pitch the thread must be accurate. Whilst s impossible to produce perfectly acate threads, we can approach accuracy y closely by means of up-to-date chines and systematic inspection.

he inspection of threads when the and high limits are very close ether is a much more delicate operan than the inspection of cylindrical k. It requires a great deal of skill, sted by some of the finest measuring paratus built. Among the thread eleents above-mentioned the effective or ch diameter is one of the most imtant, it is at the same time one of most difficult to control, it can only measured by indirect methods.

cylinder of known diameter will alys lie a certain definite depth inside h thread groove of any screw of the same diameter, and the same thread form, consequently if the angle formed by the sides of two adjacent threads is smaller or larger than the standard the cylinder will not go so deep or will go deeper, as the case may be, into the thread groove. On this fact the measurements of threads by the three wire system is based.

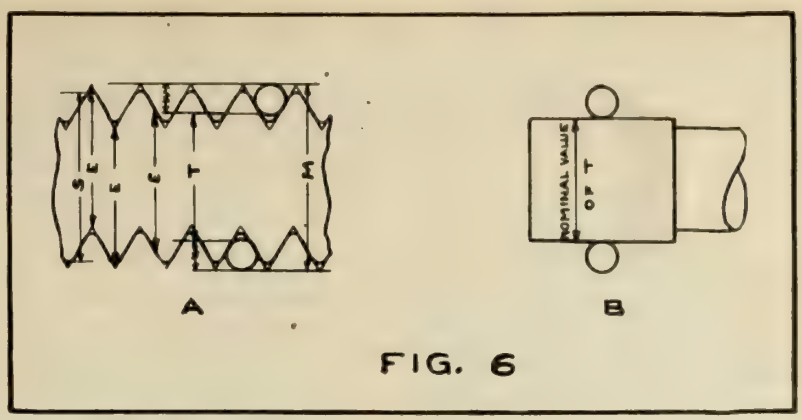

FIG. 6

Fig. 6 — Showing the wire method of measurement.

If we place three wires of the same diameter, as shown in Fig. 6. at A, the measurement over the wires consists of:—The diameter "T" of cylinder touched by the apexes of thread angles below the root diameter, plus twice the distance "S" from that point to the centre of one of the wires, plus the diameter "W" of one of the wires.

The first quantity being always a fixed amount for each particular size of screw and the size of the wire being known, any departures from the overall reading must necessarily indicate a corresponding departure in the other dimension, i, e., the distance "S" which can only happen if the form of the thread and consequently the effective diameter is incorrect. The machine shown at Fig. 7 has been designed to measure accurately and with convenience the outside, effective and root diameter of screws. Being particularly sensitive it is also invaluable for measuring cylindrical gauges, mounted between centres on the machine. Flat parts or portions out of round on such gauges can be detected quite easily. The bed of the machine consists of a heavy box form casting, machined all over to relieve any internal stress. The top face is provided with a Vee groove and a Tee slot. The groove serves as a guide for the adjustable tailstock and the saddle upon which the micrometer frame slides.

The headstock carrying a fixed centre, shown to the left of the machine, is permanently fastened down, while the tailstock is free to slide along the bed and can be clamped wherever required. The centre in the tailstock can be pushed in or out and clamped securely in position without upsetting the alignment.

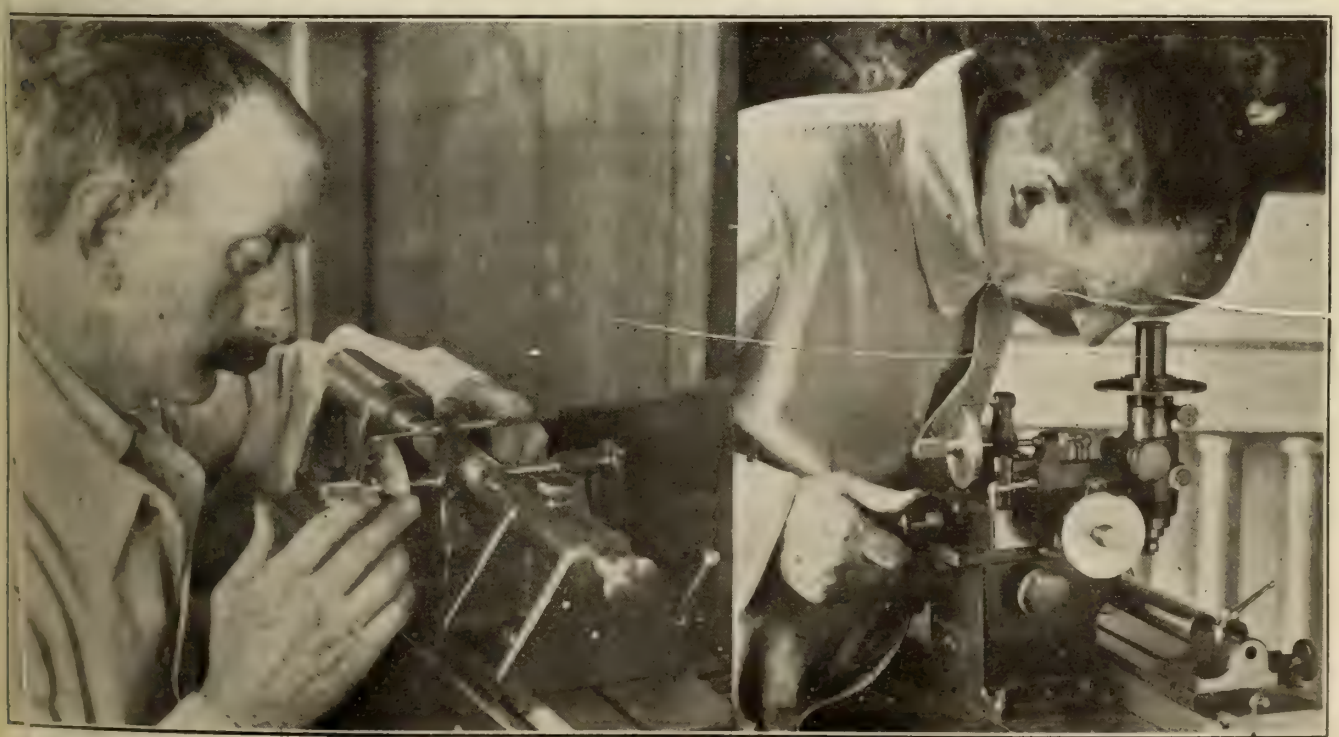

Fig. 7 — Showing type of measuring machines used.

Automobile Repair Work Can Be Made Profitable

Experiences of a Concern That Tackled This Branch of The Business—The Limits of Welding—A Fire Department Repair—Work on Aluminum—Saving Broken Drills

By DONALD A. HAMPSON

A MACHINIST should be the most competent man to do repair work, and the machine shop is better equipped than a garage back room, so why should not the smaller shops solicit automobile repair work, charging enough to make it profitable?

The city of Chicago, running true to form, has put out a number of "makes" of mail order cars. Those that had appeared were nice looking machines, though what was inside was largely a matter of conjecture, for the mail order buyer steers clear of garages. The owner of one of these cars came in our shop one morning carrying his flywheel which he had taken out himself. The wheel was of cast iron and had the starter teeth milled in from edge. About a dozen consecutive teeth were broken off and the owner wanted us to weld up the spot and cut new teeth.

We advised against this. Advised him to get a new wheel altogether or to get a steel ring to set in against a turned shoulder to be made on the old wheel. The cost of all three ways totalled about the same, and we advised against the welded repair because of the possible hard spots to be encountered in milling, the possible porous spots in the new teeth, and the fact that he would still have his cast iron teeth for clash gears. He went away.

The next day he was back with his flywheel welded, said he had found a welder who recommended such a repair but who had no way of putting in the teeth. The drawing shows the wheel in section. We didn't object to doing the work as long as the customer accepted the responsibility and paid all our charges, so we made a cast iron arbor. This had a shoulder or flange, against which a cast iron nut held the web of the wheel, which was centred by its fit on the cylindrical part of the arbor. The teeth were cut on a No. 2 plain miller. Our index centre had to be blocked up to swing a piece of this diameter. This, and the general shape of the piece, made the arrangement rather springy, a condition that was greatly relieved by clamping two angle plates to the miller table in such a position that they rested against the flywheel rim near the top, and on the side opposite from the cut. A preliminary file test showed a couple of hard spots; these were chipped out before the cuts were made.

Another Story

One of our men solicited a job from the city fire department that added considerably to our reputation. It seems that the Excelsiors had a motor apparatus that had proven itself a "lemon" and the city treasurer was getting used to paying twenty and thirty-dollar checks every time the machine left the house. It was always engine, or clutch, or transmission trouble, or sometimes a cracked case, at others a stuck bearing, and again just a clutch bushing or a universal pin. They had tried all sorts of lubricating schemes, bought a dozen advertised improvements, and realigned the parts several times; the general verdict was that the assembly was out of line and couldn't be kept in line. Engine and transmission were mounted on a sub-frame of heavy channels that extended back to the jack shaft—6-inch channels inside the frame of 8-inch channels.

A driver's chance remark gave our machinist the clew that ultimately saved the city all those repair bills. "If one of those front wheels is up four inches, I can't push the clutch out." The machinist pondered on this, and the next time he was in the fire house he took occasion to look over the mechanism. He noted that there were two universal joints in the line, each of which was fixed longitudinally. He reasoned that the frame, though seemingly heavy, must weave to some extent when the car was on an uneven surface and that this must put severe stresses in the line of action between the engine in front and the transmission, back with the jack shaft. Here was an unbroken line of steel between two fixed points. If these two points remained fixed with only an imaginary line between them, the length of the latter must necessarily change with a weave in the frame. Explaining this reasoning to the fire chief, permission was obtained to change one of the universals to a sliding type which would allow the imaginary centre line to change as per conditions. All the troubles in the major units concerned automatically ceased with the change.

* * *

A certain shop had long used a well-known brand of packing for general engine and boiler work. When they began to take in auto work, it was but natural that they make use of the stock on hand, and in the case of circulating pump packings, which autoists find very troublesome, they used the same brand to great success.

* * *

One thing peculiar to automobile repairs is the work on aluminum cases. The machinist is frequently called upon to retap holes in these cases, either for screws or studs — holes in which the threads have become badly worn. In every case, these retapped holes should be made U.S. standard threads and not S.A.E. threads. Aluminum and its compositions are so soft and granular that it is difficult to tap holes and get even as good threads as in cast iron; so when the thread in aluminum is made it is usualy somewhat ragged—now, if a roughly threaded bolt is run in this hole, the strength is lessened again and by the time a full load is applied to the part a few times the thread in the case strips entirely. To get more wearing surface in the soft metal, coarser threads are used and these hold very well if properly fitted.

The automobile, like other pieces of machinery, runs longer without repairs when certain parts are made a tight initial fit. A loose flywheel can never be kept tight by a key or keys. Nothing will ever remedy recurring trouble except a tight fit of the bore on the shaft. Universal joints and separate pinion gears and wheel hubs may seem to be tight when put together, because the bore fits at one or two points, or because a key holds, but unless both the bore and the key fit, and fit tightly the parts will loosen up on the first five hundred miles of running.

Leaving sliding gears and bearing fits out of the question, it may be said that the automobile is defective mechanically in that a considerable number of parts that should be press fits are made running fits in order to assemble them easily and in some cases so that the parts may be disassembled more readily

POINTS BROUGHT OUT

Machinists should be the most competent men to do repair work as their experience is valuable.

The machine shop is better equipped than a garage back room, so that it would pay the small machine shop to solicit automobile repair work, charging enough to make it profitable.

The question of proper fitting is most important. Both the bore and key should fit, and too much should not be left to the key alone.

The shop that goes after automobile work is sure to encounter the rush-work fraud. Learn to distinguish between a bona fide hurry job and one that is not—then let the man who is fooling you wait his turn and do not depart from this rule.

for inspection or repairs. Take universals, for instance; these should be the tightest kind of a fit on the shaft with their keys made so tight that it would take a two-pound hammer to drive them home—but in practice the universal is frequently split through the hub and a binder screw used, while the key is a piece of ⅜-inch C.D.S. slipped in a ⅜-inch keyway.

Woodruff keys are dropped in seats milled by cutters of the same nominal size, leaving a fit that is a plain botch job, no matter what the name of the car. Wheels that have taper bored hubs and a square key to drive are another example of poor practice. In any other line of machinery, that wheel would be pressed home so tightly that it would drive the car without the aid of a key but we ordinarily find the automobile hub just slipped on with a nut loosely tightened behind it and a key inserted that may be pushed in with the fingers. Little wonder that five thousand miles shows the hub worn, its keyseat "chawed" beyond repair, the key worn down a thirty-second, and the axle keyseat so bad that it has to be recut a sixteenth larger. So, if you would do lasting work, make an original drive or press fit on every part that is to transmit power, be that part wheel, gear, bolt, nut, key or shaft.

* * *

The twist drill stands up under more abuse than any other small tool in the shop. And when used in electric or hand breast drills, they are most severely tried, due to the carelessness of the workman in holding and forcing the drill. When in a drilling machine, the drill is maintained in a fixed centre line of action but the ordinary workman's centre line may swing fifteen degrees to the east and the west, all in making the same hole. That the number of drills broken on such work is not doubled speaks more for the quality of those tools than for the skill of the workmen. One shop follows the practice of saving broken drills; these are sorted and reground, then made up into complete sets just as new drills are cut. These short drills are issued for portable electric drill work and no others are allowed in these electrics. They work fully as well, and the saving effected has been remarkable.

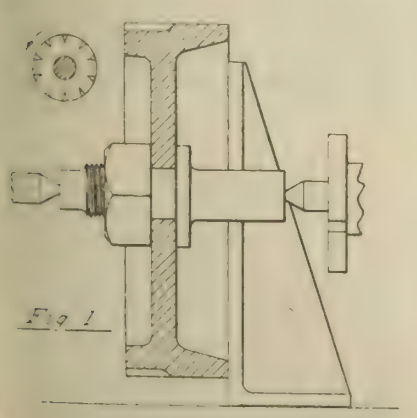
Some Further Hints

Sometimes the slots in a castellated nut do not line up with the hole in the bolt—the slot ahead makes the fit too tight, the slot behind makes it too loose. If the nut is removed and its face treated to a few passes with a good file, it will be thinned enough to allow the cotter to enter the slot ahead. The satisfaction from well doing is sufficient reward for the effort involved, even if a person was not interested in doing a first-class job.

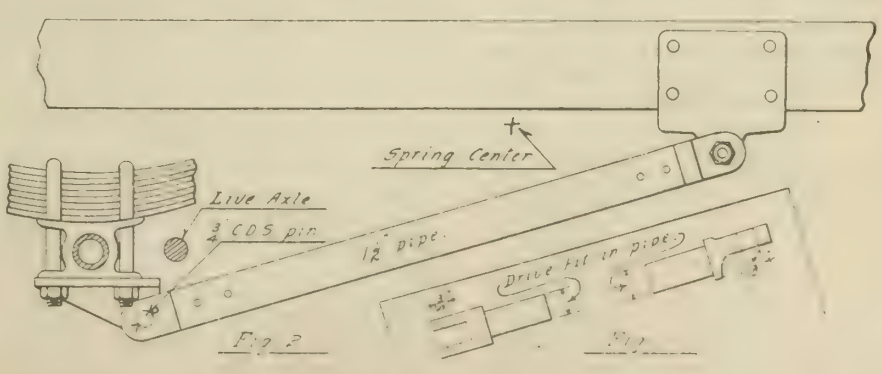
* * *

A great many cars and trucks are built with the "Hotchkiss drive," a construction in which the impulse of the axle is transmitted to the body or frame through the springs alone. All other cars have two members attached to the rear axle housing and extending forward, one to each side of the frame or else coming together V-shaped and fastened to a cross member in the centre. These "radius rods" relieve the springs of the drive; they are pivoted at each end so that the axle is free to move up and down, and it always remains at the same distance from the forward joint.

This type of drive is simpler, cheaper and lighter, but it has an objection, in that as the body load increases the axle moves backwards (the spring is fixed at the front eye which forces the centre bolt back as the weight straightens out the camber of the spring). As the axle moves back, the brake rods necessarily change also, this change bringing the bands closer to the drums—as a result, with a heavy load the brakes take hold much quicker and there isn't the movement of the foot pedal. This change in axle position makes it impossible to adjust brakes so they grip the same with full load as with no load and so they grip as well backing up as in forward motion. On some cars, this latter is so marked that they have no brake at all when backing—very dangerous in a hilly country.



We changed a three-ton truck over from such a drive. The owner said the difference was as the difference between black and white. He never felt safe when one of his men had to go outside of the level centre part of town—now they can go anywhere, carry anything and always have brakes. Our bill for the job was $62. A drawing and description of the work follow and they may serve to guide others who would like to do the same thing, but hesitate.



Our rods were made out of 1½-inch pipe. This is about 2 inches outside diameter. Pieces of steel were turned to drive in these pipes at each end and were secured further by cross rivets. These steel pieces had projections that were shaped up into rod and eye ends which were in turn joined to the fixed chassis members by means of pins. On this particular truck, the best way to fasten at the axle was to make longer spring clips and bolt steel angles to the under side of the axle housing. Cast iron saddles were used at the forward end and these were riveted to the frame channels in the customary manner. Plain pin joints were employed; a better job would have been ball-and-socket joints, but the extra expense was not warranted.

As the truck was of the shaft drive type, no adjustment for length was needed, as it would have been if the drive had been by chain. In doing such a job, it is best to have the rods short—the longer they are, the less do they follow the movement of the spring up and down and slightly backwards as the load settles the spring.

* * *

The shop that goes after automobile work is sure to encounter the rush-job fiend. It is a very strange thing that a man will arrange for a sitting with his dentist weeks ahead, he will cheerfully bargain with the plumber or the carpenter to do some repairs to his house "next week," and he willingly agrees to have that ton of coal he needs so badly brought around as soon as the roads are broken—but when it comes to a repair job on his automobile, he has got to have it started inside of ten minutes. If he can't get that, he hollers as though he were being robbed and he regales his friends with the news that "there ought to be at least one shop in this town where you could get a job done promptly and not get soaked for it." This rush-job man is an unprofitable customer for any shop. Learn to distinguish between a bona fide hurry

The three sketches are fully explained in text.

job and one that is not—then, let the man who is fooling you wait his turn and do not depart from this rule.

* * *

Workmen, and others, are apt to judge a car's braking power by the size of the drums. As a matter of fact, size has nothing to do with it—pressure perpendicular to the surface of the drum is what counts. This pressure remaining the same, an increase in drum size means longer life for the drum and the linings.

* * *

A fellow came in the shop one day for a little work on his car which involved our going out and looking under the hood for a measurement. In so doing, we noticed an unfamiliar wire running from the radiator and another from the crank case; both led up to the dash. Asked what these were, the owner replied, "You see, the car is an old one and has no dash oil indicator and no motometer. I have to get out and look to be sure my oil and water are high enough. Well, I borrowed the idea from our farm lighting system which has a cut out switch that stops the ignition when either the oil or the water gets low. It works all right and I like to fuss with those things even though I don't expect to depend on them to tell me when my engine is in danger." There are a good many people driving cars who know little else than how to press the starter button and fill the gas tank and who would profit immensely if such a device were made part of the car in the beginning.

* * *

The motoring public looks for more careful workmanship in the machine shop than in the garage and expects greater attention to details. Machinists should play up to this good opinion of them. One way is by being careful of the finish of any car they are working on. If working on the engine, for instance, a cloth should be spread over the fender and adjacent section of the running board—then when greasy tools or bolts are laid down on these parts, scratches and grease spots are avoided; a wrench that slips is guarded from the customary result of scraping off a generous portion of paint. Another paint protector is the leather topped jack; half an hour spent in riveting a piece of old belt leather to the top will prevent scraping the paint off axles and rods and the nickel from hub caps.

* * *

Bronze bushings for automobile work usually have a relatively thin wall. This fact, plus a little trick, will often help out when there is no supply of bronze to draw from and a bushing is needed in a hurry. Suppose a bushing is wanted for a shaft that has been worn and ground true again, making it a few thousandths under size and the only bushing or blank available is one piece that already has been reamed to the nearest sixteenth above—how can that blank be reclaimed?

Turn the outside diameter to, say, ten thousandths over some standard size—then drill and ream a hole in a piece of cast iron to that standard size. Scrape or countersink one end of the hole bell-mouthed and file one end of the bronze a little tapered so it will enter the hole. Put oil on the outside and force the bushing through in an arbor press or a vise. It will be found that the interior of the bushing is smaller by about two-thirds the amount that was left on the outside of it. There is a limit to this process but if there is material enough on the outside, the bushing may be further compressed by successive forcing through smaller holes. And a bushing that has been spoiled by boring it too large may be salvaged in a similar manner.

* * *

One of the most useful tools for automobile work, and in fact for general repairs, is the gooseneck style of screw straightening press. The conventional arbor press and the heavier two-post style of press are found in all shops but for straightening shafts both of these are outclassed by the third type referred to. This tool, which does not seem to be very well known, has an open side facing the workman with a rather long flat bed extending from right to left. On this bed are placed the fulcrum blocks, adjusted to suit the bend under repairs, and directly above the bend is the screw for forcing the piece back to straightness. Centres, adjustable along a convenient rod, are provided for testing the piece without the workman leaving his position. The screw is fitted with a hand wheel for quick movement and a bar for powerful impression while graduations on the wheel enable one to gauge the amount of pressure applied for successive trials on a stubborn piece. Every shop that does auto work should make or buy a press of this type.

MEASURING METHODS

Continued from page 27

ment. The tailstock is clamped by means of a lever which tightens a bolt inside the tenon groove. The saddle is provided with two Vee grooves to accommodate two rows of steel balls, upon which the micrometer frame rests. The micrometer frame has a groove of the same shape as that on the saddle and a flat which rests on the other row of balls. The transverse motion of the micrometer is perfectly smooth and free. The Vee grooves for all the balls are cut on steel strips, hardened and ground.

The micrometer is furnished with three anvils. One of the anvils measures from zero to 1-in., another measures from 1-in. to 2-in., and the third allows measurements from 1¼-in. to 2¼-in. to be taken. In order to set the two last anvils correctly suitable gauges are used.

The micrometer head is adjustable to enable the operator to set the micrometer to zero. The thimble carries a large graduated disc reading to .0001-in. Above the micrometer there is a fixed index pointer to read the graduations on the disc and a rod from which the wires are suspended. The measurement of outside diameters is naturally a comparatively simple matter as the position of the micrometer in relation to the work ensures correct readings even with a two point contact.

For measuring the root diameter two special adapters as shown at B, Fig. 6, are used. They are hung from the rod on the micrometer frame. The adapters are made of steel, hardened and ground, the threads being relieved so as to ensure the points coming in contact with the thread root without touching the flanks of the threads.

For measuring the pitch diameter the following formulae can be used:—

$$M = T + 2S + W.$$

in which M is the reading of micrometer when measuring over the wires, T is the diameter of cylinder touched by the apexes of thread angles below the root diameter. S is the distance from that cylinder to the centre of the wires, and W is the diameter of any of the three wires.

For Whitworth threads $S = \frac{W}{.9235}$

From the formula given above another formula can be derived which is more convenient in working:—

M=D—1.6008P+3.1657W For Whitworth threads

M=D—1.5155P+3W For U. S. or metric if pitch "P" is given in inches.

M=D—1.732P+3W For the sharp V threads.

The wires used must not be smaller than .506P or larger than .840P.

$$P = \frac{1}{\text{number of threads}}$$

If the measurement over the wires differs from the results obtained according to the formula, the effective diameter is incorrect by the amount of the difference between the reading and the standard.

These two methods will suffice for the present, and in a later article we shall discuss "Modern Types of Gauges And Their uses."

The first part of the programme drawn up for the electrification of the Japanese Government railways, which is to be begun during this fiscal year, is said to embrace 203 miles of railway and to cover the various routes in the neighborhood of Tokyo and Osaka. The work is to be completed by 1926 or 1927, and the amount of power required will be 70,000 kilowatts, all of which will be obtained from power stations erected by the Government. A station of 15,000 kilowatts capacity is now being built in the suburbs of Tokyo.

Another Demonstration of Canada's Progress

New Extension to Meet Increased Demands—Large Foundry—Description of Different Castings Completed—Paper Machinery is Made—Photographs Showing Specimen Castings, Molds And Equipment

OF RECENT years Canada has been developing along lines hitherto considered beyond her reach ut each stride convinces not only the anadians but those of all nations that anada is becoming a nation to be reckned with.

From the standpoint of natural reources it has always been known that e possessed an enviable share, but our xtreme modesty and lack of self esteem as prevented us from making much use f them, or would it not be more fitting o say that the lack of gumption on the art of our immediate forefathers stood n the way of our natural resources eing developed to the advantage of our eople.

It has always been a strange trait of he Canadians to want outside capital nd outside brains to do all our develping. The recent print paper fracas owed us that our pulp wood forests ere the reserves on which outside pubishing houses depended for their supply of paper, but it also showed us that hile these reserves are within our borer and under our flag they do not beong to us. This, of course, is only true f certain sections.

We still have lots of pulp wood which as not been thrown away, and we have he natural water power and electric ossibilities to develop it and work it p, not only into pulp, but into paper is ell. Different concerns in Canada have or some time back been making pulp achinery, but the machinery for makg the paper has been for the most art, imported. The same might be said f the water wheels. Canadian institutons have been making turbines for ears back, but not going extensively in the larger sizes such as are now called r, but this also has been changed and me large contracts have been taken by anadian establishments and delivered a most satisfactory manner.

To meet the increasing demands for ese large engineering contracts the ominion Engineering Works, Limited, Rockfield, Que., have recently exended their grey iron foundry, which the present time is capable of taking re of work of every character from he smallest to the largest castings. any one-piece castings weighing close fifty tons have been successfully oduced, and orders now in hand call r pieces that will approximate 60 tons weight for one casting. The original undry, whch was about one-half the ze of the present building, was opened out sixteen months ago, the first heat eing run off on the 10th. of January 920. At that time the castings produced were intended for paper making machinery and small turbines, but the activities of the company during the past year have expanded so that greater facilities were essential to meet the prowing demands for larger and heavier castings.

Different Castings

Most of the castings required for water turbine work are of a most difficult character, and it is for this work that the foundry has been particularly organized. Such intricate castings as turbine runners, head covers and speed rings require equipment and expert moulders not found in most foundries. The Dominion Engineering Works is now building turbines of the largest sizes yet built, as well as smaller wheels.

The foundry building, which is located at the eastern end of the general machine shop, and at right angles to it, has a total length of 346 feet, 6inches, and a width of 145 feet 6 inches the width being divided into three sections, two side portions of 30 feet width, and the center section, where the heavier work is prepared, having a width of 85 feet 6 inches throughout the entire length. The height from the floor to the central roof truss is 41 feet, while each side section has 24 feet 6 inches clear below the roof supports. The side farthest removed from the main shop for a length of 180 feet is reserved for the blower room, cupolas, core drying ovens, sand mixer, etc., while the charging floor extends above. The total foundry floor space is approximately 29,400 square feet, and that available for moulding purposes is close to 28,000 square feet, divided into a number of sections of different size, each division intended for different classes of work. The main floor is served by three cranes of 70 tons, 35 tons, and 15 tons capacity, travelling throughout the entire length.

For the production of the large paper making machines pits were necessary for the making of the large drying rolls on each. Two of these pits have been provided, one having a diameter of 12 feet 9 inches and 16 feet deep while the other has a diameter of 9 feet 4 inches by 12 feet deep, both being lined with steel plate, and located at the north end of the foundry. In addition to these pits being used for the moulding of long drums they were also utilized for the making of the built-up cores. Adjoining these pits are special core ovens in which the prepared cores for the dryer rolls are placed on end. This section of the shop is also provided with two wall jib cranes of 3 and 5 ton capacity. Directly opposite the cupolas and about the center of the main floor is a 72 inch by 72 inch pneumatic jolt ramming machine. This is conveniently located for serving both the main floor and the side section.

At the west end of the main floor are located the concrete pits for casting the large water wheel and generator sections. Five of these pits are of uniform size, 30 feet by 16 feet, while one on the end for very large work is 34 feet by 30 feet, the depth of 12 feet being common to all. The reinforced walls are 18 inches thick. For mould preparation and the setting of cores, a five-ton Dominion Bridge gantry crane straddles the pits and travels over the entire six. For the removal of the finished castings the large travelling crane is used. Some of the work is shown in the accompanying views.

The cupolas, three in number, are located about midway of the length and directly opposite the entrance to the machine shop. The cupolas are 37 inches, 54 inches, and 84 inches in diameter respectively, with capacities of 7½ tons, 15 tons, and 25 tons of iron per hour, and were built by the Dominion Bridge Co. Three blower units, with capacities of 13 cubic feet, 24 cubic feet, and 81 cubic feet of free air per minute are provided, and they are so arranged that any one of the three may be used for any cupola. This is one of the best features in the entire plant, and one which is too frequently overlooked.

Directly above and adjoining the cupola section is the charging floor which has storage facilities for 100 tons of material. On the same level as the charging floor and extending out over the material stores section are two loading platforms, each 16 feet 6 inches in width, and with a length of 21 feet, half of which protrudes outside the building. The material storage space occupies about 35,000 square feet. The coke, scrap and pig iron, from the yard are loaded into skips handled by a 15 ton bridge crane operating over the entire yard. When the skips are brought to the loading platform the material is loaded into buggies with the proper proportion of each material, and weighed before going to the cupolas. Foundry sand is also delivered in this way and dumped into the mixer located below the charging platform.

At the south end of the foundry is the flask storage yard, where heavy flasks and moulding plates are kept. An interesting feature in regard to wall construction is shown at this end, where the brickwork is only built part way up to facilitate the handling of the large

flasks to and from the foundry. The crane runways extend out over the storage yard so that the crane can run past the wall without trouble, the hanging material entering through the large central swinging doors. Overhead doors are provided for closing the space above the partial wall, but during the summe

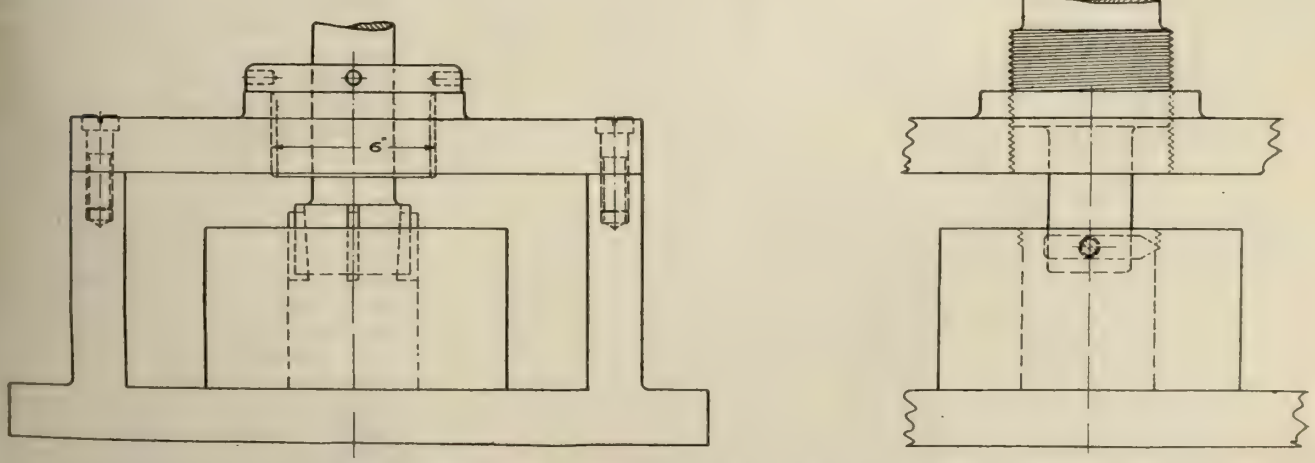
What Is A Drilling Job?—An English Opinion

THE DRILLING machine has remained a surprisingly simple tool when compared with some other machines, according to R. S. Mallison, and yet, as he says, its range and capabilities are almost unlimited. Speaking on the subject of "What is a Drilling Job" he states in British Machine Tool Engineering, that amongst many unusual operations he has seen executed on the radial drill, the ones shown in the present article are particularly worthy of mention. He states that in the one case the work was mounted in a special jig or bridge, in the top of which was a pilot hole with a standard thread. When drilling and opening out the hole by bar and cutter, a bush was screwed into the pilot hole, being taken out for threading operations.

A bar with a master thread was used, fitted with a single cutter, the threaded portion of the bar engaging with the pilot hole threads just before the cutter enters the work. When the spindle is started the tool, of course, automatically feeds down to cut the corresponding thread in the work. I saw a 5 in. diameter hole bored and threaded by this method, with accuracy and in about one third the time occupied for the same operations on a lathe.



On the other occasion the setting lugs of aluminum gear cases for motor waggons were being sawn off. A horizontal circular saw was fastened to a morse taper shank, which latter was cottered into the drill spindle. The spindle was then adjusted to the correct height, the friction applied to hold it from slipping, and the lugs sawn off by moving the radial arm. This method gives quite good results besides eliminating the necessity for moving to another machine.

Particularly interesting is the machining of connecting rods in locomotive shops. A special tool usually known as a "D" cutter is employed to cut out of the solid, a lubricating well about 2½ in. diameter, leaving a solid piece of metal in the center. The latter is then drilled for the syphon, and the outer face of the well is threaded for the purpose of screwing in a cap. All these operations are executed on the one drilling machine.

What is known as a "D" cutter.

By the use of a simple form of tie-rod the heavier radial drilling machines can be immediately converted into a rigid form of vertical boring machines. Cylinder boring is executed to advantage by this method, various forms of cutters being employed. Large holes are bored in steel and wrought iron jobs which could not be accommodated on horizontal borers without some difficulty, and,

Showing the jig used for drilling, opening out and threading.

in many instances, with an appreciable saving both in setting up and machining times.

On one occasion the writer saw a box body vertical drill with a compound work table, on which was fastened a universal chuck, used to distinct advantage for boring blanks and flanges. The users were enthusiastic about the job, for it was saving both power and time on an expensive turret lathe. Trepanning is another operation usually assigned to the radial drill. A pilot hole is first drilled in the center of the job, which acts as a steady hole for the trepanning tool. This latter has two adjustable cutters, carried in a horizontal slide, which are set to the diameter of the hole required. By this method it is possible to cut out a hole up to twenty inches diameter in cast iron on the heavier radials. On one particular occasion the writer noticed trepanning operations being executed on crank webs without the use of a pilot hole, a specially strong tool being employed. The finished hole was 14 in. diameter, and the metal removed was then machined for another job. This procedure must have resulted in a fairly considerable saving each year.

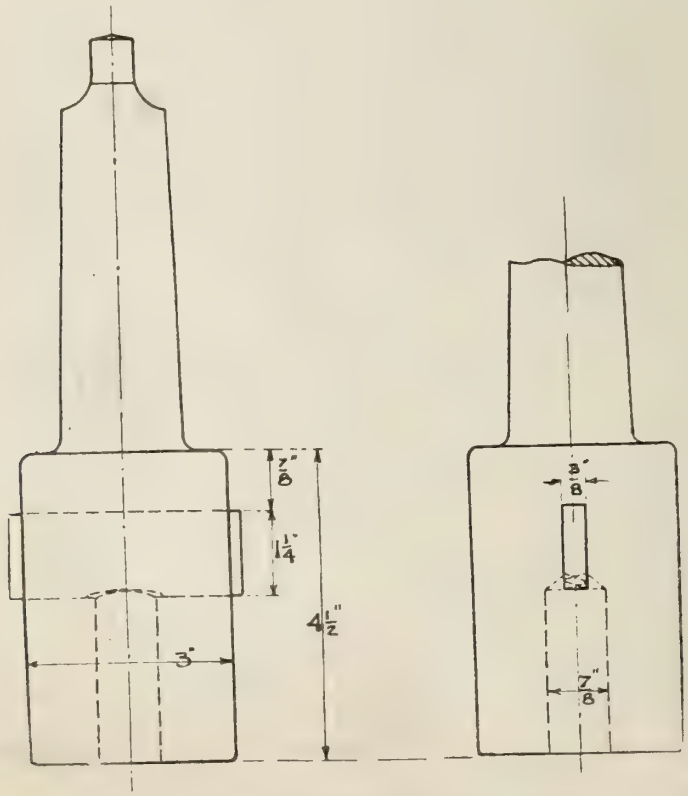
The improved powerful friction on Asquith radials, for instance, makes them suitable for milling and keyseating to a surprising degree. The spindle is securely held by this friction arrangement, thus preventing it from slipping. The milling cutter is horizontal, of course, and the traverse is obtained by the movement of the saddle along the arm. The use of tie-rods gives rigidity for this work. The vertical drilling machine with its compound work table has even greater advantages than the radial for these operations, as the work can be accurately adjusted both longitudinally and transversely. In one particular instance, to my knowledge, an Asquith box body machine is used practically as much for milling and keyseating as for the ordinary run of drilling jobs.

ANOTHER DEMONSTRATION OF CANADA'S PROGRESS

(Continued from page 32.)

months it is left open, thus giving maximum ventilation for gases, etc.

The roof over the casting pit is of concrete, this doing away with the necessity of sprinklers, but the latter are provided in all other sections of the plant. Between the foundry and the machine shop is a space 41 feet wide and 347 feet in length, where the cleaning room is located, together with a general storage bay for finished castings before the same are delivered to the machine shop. This section is served by a 40-ton travelling crane.



Standard gage railway tracks are laid directly into the shop and this assures economic handling of all material and heavy castings. Convenient track scales are located in different parts of the shop. The smaller castings are cleaned by a Pangborn sand blast, while the larger ones are handled with a wire brush.

Every attention has been given to the welfare of the workmen; a large locker room has been provided with wash basins, where the men may clean up and change their clothes.

On the whole, it must be admitted that this plant compares favorably with those of any country and speaks well for Canadian ambition and confidence in Canada's future.

In the illustrations will be seen some views of the interior of the foundry, showing the style of work being done, the method of doing it, and the facilities at the disposal of the men for accomplishing the same. The one marked E-46 is half of a head cover for a twenty thousand horse power turbine water wheel. Compared with the gentleman who stands beside it, and who by the way is Mr. Cahill, the foundry superintendent, it is a fair sized piece of casting. In the rear of this casting and in line with where Mr. Cahill is standing will be seen a grab bucket which was not mentioned in the list of equipment. This is just an incidental which is expected to be found in a plant of this kind. Pits are not filled nor emptied these days with a hand-operated shovel.

Another good sized casting is shown in E-70. This is half of a speed ring and makes a better showing than the other in comparison with the workman who stands in front of it. E-50 shows a commencement being made on the mould for the speed ring just mentioned. E-42 is a typical loam moulding floor, while E-118 shows the large casting pits, and the moulds in various stages of completion for the large turbine castings. E-9 is a view of the north end of the foundry showing pits and the round sectional flasks used for moulding and casting the long paper mill drying rolls which are poured on end in these pits. E-16 is a general view of the foundry interior, showing the jolt ramming machine in the middle of the floor and the drying ovens in the rear. E-117 shows the battery of cupolas with a combined capacity of 47½ tons per hour.

Showing the tool used for ending studs.

KILLING ATMOSPHERICS

One of the most troublesome difficulties in wireless telegraphy is the interference caused by what are known as "atmospherics." The receiving instruments are affected by electric waves which arise no one quite knows how. They are worse during the day than at night and also during certain weather conditions. For many years a British company has been striving to overcome this difficulty and it has at last been rewarded by the discovery and perfection of a device by which the effect of "atmospherics" can be quite eliminated. What this means in practice is that existing wireless stations can carry far more messages than they have yet been use of automatic signalling at high speed had to be given up and oral reception employed, owing to the way in which the atmospherics played havoc with the machine records of the signals. A skilful operator could disentangle the human signals from nature's freaks, but the speed at which an operator can receive is limited.

WHAT OUR READERS THINK AND DO

TREATMENT OF UNDESIRABLE WORKERS

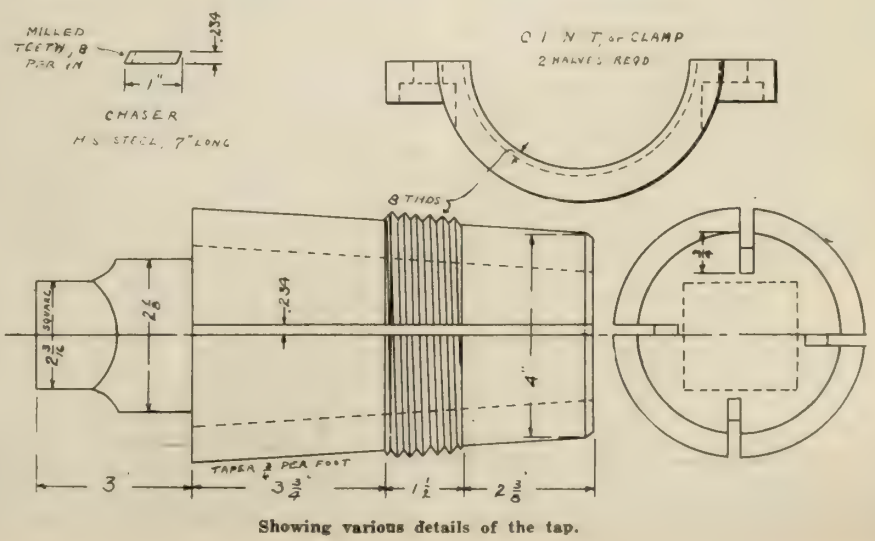
By JOHN HOMEWOOD

I have just had a chat with a man who has been hobbling around for the last few months on a pair of crutches, as he had met with an accident in falling from a scaffold. He had been on the job but a little while when the misfortune happened. But, prior to this job, he had been discharged from a manufacturing plant as an example to others; he had committed an industrial crime known as doing "government work."

The fact that he was going round on crutches does not have any particular bearing on the issue I bring forth, but the case serves as a practical example of the dangers confronting a workman discharged from a plant under the condition mentioned. A man's last employer is of vital importance in assisting to secure another position, and his opinion is looked upon by most people as being the most reliable recommendation. It was unfair to the man not to give him a fair chance to make good. Had his record been spotless prior to this offence, the injustice becomes greater in not giving him another chance to prove up. How much more benefit could have been obtained had the offender been summoned to the office and given a talking to that would have sown a seed of self respect in the man's mind, which would have grown in volume for the benefit of himself and the man who had shown him leniency. It is only necessary to apply a little grease to the track of a worker to see him slip away, unless he is equipped with an emerency brake in the form of "forming his own opinions." Tactless decisions from the mouths of men who cannot see any farther than the length of their nose, are as so much rich fertilizer spread upon barren soil in preparing the worker's mind for the growth of oppression and antagonism. Why should we apply penalties to offenders in industry who have taken their first wrong step, when other means could be applied that would be a benefit to both him and his employer. The policy of "setting an example" creates a spirit of distrust in the employer and one of revenge in the other.

Why should a petty offence justify an effort to tear at the heart of a man's honor? It destroys that which we are trying to gain, namely, confidence and good will between employee and employer. You may fire a man from your plant for being dishonest but it will not correct the malady. The next man that hires him will probably suffer greater than you as the consequence. It is often not the man's fault, but yours, as you haven't given him his chance. Men are born with good qualities in them, and it is up to employers to get them out. The days of the club and coercion are back numbers to modern ways of thinking; we have got to meet our issues in another way; we have to use methods of construction; construction of morale, not destruction of character. An employee whose loyalty is "bought" with deeds of kindness coming from the heart is worth a hundred smiling ones who eagerly hang around waiting for their regular check.

INSERTED BLADE PIPE TAP



By DONALD HAMPSON

Where pipe fittings are manufactured, and in plants that have to tap many holes for pipe, the outlay for taps is a considerable item. It is doubtful if there is any better way for the smaller sized holes than to buy stock taps and keep sharpening them untill they can be ground no more—then to throw the taps away. Bigger taps handled this way run into quite a bit of money and it is for the purpose of helping others save, that the tap shown herewith is presented.

The tap is of the inserted blade variety and uses three, four, or five blades according to diameter. The blades, or chasers, are made of high speed steel; they are not machined except for cutting of the teeth, which is done by a hob in a milling machine, holding several chaser blanks at one time, on the angle in a special fixture of conventional design. An economical feature is that all the chasers are alike and may be used interchangeably in any of the tap bodies from 2½ inch up. After milling the teeth, the chasers are heat treated and stored in the tool room.

The bodies are turned from machinery steel, slotted for the chasers, and squared on the driving end to suit the driver in the tapping machine, or carried in the spindle of a drill press. The dimensions given show the 4 inch size; other sizes may readily be taken from this as the taper is the same for all, and so is the length. The threaded portion serves the double purpose of positioning the clamp for the chasers thereby aligning the chasers to the correct spiral.

When assembled, the tap shows a little more than two inches of cutting length at the small end of the taper. The teeth nearest the end dull fastest, and these are ground off when they retard production and the blades are all shoved down so many threads. The construction is as near fool proof as can be made; it is simple; the parts are interchangeable; and the design is rugged and free cutting.

Showing various details of the tap.

THE REMEDY FOR CASTING TROUBLES

By JOHN S WATTS

REPLYING to the article entitled "A Recital of Casting Troubles" by Donald Hampson, on page 40 of Canadian Machinery dated July 21, 1921, having been through similar experiences to those given in Mr. Hampson's recital. I can appreciate his feelings in the matter, but in my opinion the remedy is in his own hands, and a fair part of the responsibility for his troubles rests upon his own shoulders.

To start with, no matter how much we may preach about the foolishness of tuning out work of a poor quality, the firm that is working on a small and uncertain margin of profit will never turn out as good work as will one that is assured of a reasonable return. It is common knowledge that iron foundries, whether independent or run as part of a manufacturing plant, are subject to intense competition and do not make the profits that other departments can. Because of the small capital involved in starting up a foundry, there being very little machinery required, the business attracts the mechanic with a small stake, and being able to operate with little or no overhead expense, he can cut the price to the bone. The small operator being usually innocent of any knowledge of costs and book-keeping may run for some time before he finds that the prices he is working for are losing him money instead of being profitable as he thought. By the time sad experience has proved to him his mistake, some other fellow like himself has started in, and this competition in turn prevents his raising his prices to a fair figure. It seems probable that foundries will always be subject to these conditions, and that the only way to get a good grade of castings is to have them thoroughly inspected at the foundry.

There are so many different defects to which castings are subject, and frequently many of these defects are of little or no importance as regards the final utility of the casting, that the majority of foundry men come to look upon all but the most serious defects as mere trifles, which can be overlooked. It is but human for any man to be lenient in the inspection of his own products, and anyway a molder is seldom sufficiently conversant with the ultimate purpose to which the casting is destined to really form a competent opinion as to what defects matter, and what do not, and will naturally give the casting the benefit of any doubts he may have.

Routine at Fault

The regular routine of sending a pattern to the foundry with an order for so many castings off it, gives the foundry no inkling of what will pass or what will be condemned, and with such a number of faults as a casting may have, it is impossible to write out a specification that will give the foundry man an idea of what will be passed unless we demand absolute perfection, and if we do, the price would make us think the castings were to be of solid gold.

Then there are defects such as warping of the casting, which may or may not be fatal, depending upon whether they will clean up or not, and to determine if the defect will machine out may require surface plates, gauges etc., which it would be absurd to expect the foundry to supply out of the price received for the castings. It seems only logical then that the purchaser should do the inspecting of the castings, and that the inspector should be on hand at the foundry when the first lot of castings are run through. This will give the foundry a chance to find out at the start what is required, and avoid the heavy loss incurred by making up the whole order with defective castings. It may seem to some that the loss due to making defective castings is borne directly by the foundry and is no concern of the purchaser, Experience however proves that the cost finally falls upon the purchaser, because when the foundries find out that, for any reason whatever the castings ordered by a certain firm infallibly bring a higher than usual percentage of reductions will raise their prices to compensate for this loss. Indeed we will always find in every district some one firm that is always quoted higher prices on its enquiries than any of the others because of some fault in the management which causes work executed for them to cost more than similar work for other firms. This fault may be lack of clearness in their requisitions, unusually high percentage of rejections, faulty design of the work to be executed, or what is probably the worst fault, the impossibility of foreseeing what slight defects will cause rejection.

The point should be well drilled into all employees of any firm ordering much material from outside firms, that the easier it is made for the contractor to furnish satisfactory goods, the lower will be the prices which they will quote, and that any obstacles or difficulties placed in the contractors way will infallibly be ultimately reflected in higher prices, to be paid by the purchaser.

A good inspector, which means a man who knows exactly what will injuriously effect the functioning of the parts he is inspecting, and what defects are of no importance, will, by preventing loss of time in continuing to turn out castings that will finally be rejected, be able to greatly expedite the deliveries, and ultimately the firm employing him will get their castings for a lower price, and of a suitable quality.

It may be objected that inspection will incur an additional cost greater than can be borne. Where quantities of the same piece are to be purchased, experience proves that inspection at the maker's actually lowers the final cost, and the experience of Mr. Hampson, who states that bad castings cost him $6,000 last year is a case in point, as the total cost of inspection could not very well exceed one third of this amount.

A GOOD IDEA

The Fosdick Machine Tool Co. have a good plan of transporting their machine tools to the testing department. They built a special testing outfit and mounted this on a three wheel truck. This truck has four lag screws that are driven into the floor to anchor the testing rig in place for use. When it is to be moved, it is only necessary to disconnect the electric feed wire, loosen the lag screws, and connect the pulling handle to the swivel or third wheel, which is arranged to make a complete revolution when it is necessary to turn short in the shop.

When a machine is to be tested the 3-wheel truck is set at right angles to it and belted up. An idler pulley makes the use of a very short belt possible. A friction clutch controls the transmission.

CLEANING BURRS FROM THREADS

We had a screw used in our manufacturing that was milled flat across the end after it came from the automatics. The amount removed varied from 1/16 to 1/8, which was necessary to bring the starting of the thread in relation to other parts. After milling, the burr had to be entirely removed from the last thread to facilitate assembling. This was a slow, laborious job as accomplished with a file. The thread was a special 29 degree type.

The head of the department hit upon a scheme for removing these burrs that is worthy of wider use. We had sectional wire brushes, eight inches in diameter, that were used to clean up discolored drawn brass and steel parts and were discarded when worn within half an inch of the flanges which retained the bristles. A section of such a worn brush lying around served as the germ of the idea that proved so successful. One of these mounted on an emery stand became instantly a flexible, revolving file. With the screws resting in a V rest just at one side of the brush, they were revolved by hand against the wire brush and every particle of burr cleaned from the thread in an instant. The little burr thrown up, or left, on the end of the screw was unimportant. Ninety-five per cent. of the former time was saved and a better grade of work performed.

WELDING AND CUTTING

Production Welding of Varied Steel Products

Gas Welding Industry Has Made Rapid Progress—Method of Welding Barrels—Housings—Tapered Tubes and Other Articles —Types of Machines Used—High Speed Welding

THE rapid progress made in gas welding in the past ten years and the wide application it has found in industry is a subject too broad to cover in detail in any small space, so I will confine my remarks to the machine welding of steel products. The advent of gas welding has gone down in industrial history as a memorable event which marked the resurrection from the scrap heap of much valuable equipment which could not be restored to service by any process known to industry previously. And, for a considerable period of time application of the art of gas-welding was confined to reclamation work and job welding on a small scale. But industrial leaders soon saw the possibilities of the process in production work and hand welding was adopted as a standard method of fabricating metal parts.

In due course hand welding yielded to the trend of the times and efforts were made to supplant the slow manual operations with automatic machinery. The early gas-welding machines were built for the production of iron and steel pipe of heavy gauge and usually were equipped with a pre-heating furnace in which the formed material was preheated prior to welding. After leaving the furnace the pipe passed through vertical rolls which fed the stock up to a pair of horizontal pressure rolls at which point the seam was welded without the addition of a filler by passing under a stationary welding torch which melted the two edge of the stock together as they were being held in contact by the pressure rolls.

The preheating furnace was advantageous from purely a welding standpoint but there were so many disadvantages from the production standpoint that it was discarded; hence, the present day machines in general utilize a special water-cooled multiple jet torch to do both preheating and welding with the same tip, although in some processes independent flames are provided to preheat ahead of the welding flame,—some designers going even so far as to operate a preheating torch on the underside of the seam in cases where the dimensions of the article to be welded will permit.

This type of machine can be used to weld long lengths of tubular shaped stock such as round, oval, square, rectangular and also the more complex sections such as are used for windshield frames , etc., in which the stock is of constant cross section throughout its length. The welding of barrels, housings, tapered tubes and other articles in which the cross section is variable, presents a different problem, since these cannot pass through rolls as in the case of round tubing. Two types of machines have been designed to handle this class of work, the one comprising stationary metal dies over which the welding torch is propelled along the seam, and the other a stationary torch under which the stock clamped in moving dies travels forward under the flame.

A machine of the stationary-die type can be readily built from an old lathe by placing welding dies on each side of the lathe parallel with the bed and with the welding torch supported on a swinging arm attached to the lathe carriage. In this manner the torch will travel forward over one die the length of the weld and is then swung to the opposite side of the lathe where stock has been placed in the dies preparatory to welding. By reversing the travel of the carriage, the torch will move back over the second die completing the weld while stock is being replaced in the first die for a repetition of the welding operation, and so the cycle continues. This type of machine has the widest application of any and the length of the article welded is governed solely by the travel of the carriage.

Cast of Welding Dies

The torch is secured in an adjustable holder which permits of movement in three planes; hence the operator can easily regulate the movement of the torch along an irregular seam. The cost of welding dies is comparatively low and dies can be replaced for a new job with little delay and at a small expense. However, where large quantity production is dealt with on a standard article and the size of the piece to be welded is not too great, a moving die machine will prove very economical.

Here the welding dies, either one piece or sectional, are mounted on two parellel chains which are driven by sprockets at one end of the machine and pass around idlers at the other end. One operator feeds the pieces to be welded into the dies as they move forward. The second operator regulates the torch and welds the work as it progresses under the torch. The welded articles are released from the dies as the chain passes around the sprocket and drop into a truck ready to be moved on to subsequent operations.

The welding of seams on circular, square or polygonal shaped containers can be accomplished by rotating the work under the welding torch either vertically or horizontally depending upon the location of the seam. Stock up to ¼ in. in thickness can be welded in these seam-welding machines without the addition of a filler. This in general is a brief description of the various types of seam welders in use today and gives the principles of operation of each although they will differ in detail according to the peculiar problems encountered in the various jobs.

Many modifications of the various types of welders have been built, as for

POINTS OF INTEREST

Describing Various Types of Machines used for Welding

The welding of seams on circular, square or polygonal shaped containers can be accomplished by rotating the work under the welding torch either vertically or horizontally depending upon the location of the seam.

From a welding standpoint the best commercial steel is open hearth, either hot or cold rolled, with an analysis as shown in present article.

*Author is superintendent of tube department Standard Parts Co., Cleveland, Ohio, and presented this matter before the American Welding Society.

example, a tube welder in which the forming, welding, sizing, grinding, straightening and cutting operations have all been combined in one automatic machine, but since the welding is done in the same manner as we have described we will not attempt to go into further mechanical details of each at this time.

The next problem after deciding upon the proper type of welding machine is the determination of the most suitable material from which to manufacture the article. From a welding standpoint the best commercial steel is open hearth, either hot or cold rolled, with the following chemical analysis:

Carbon ..... .05 to .15
Phosphorus, not above .... .045
Sulphur, not above ..... .050
Manganese ..... .30 to .60

(This analysis is the same as the S.A. E. specifacations No. 1010 for carbon steel.)

The steel should be free from segregated crystallation, laminations, slivers, cracks, pipe flaws, slag or oxide inclusions and other injurious defects. The surface and edges of the stock should be free from lime, rust and dirt which will form slag inclusions in the weld and decrease the cohesion of the metal as well as retard the action of the welding flame.

The above specifications can be revised to get higher carbon and manganese contents when required in the article to be welded, but the sulphur which causes the most trouble in the welding operation, should never exceed .050 or you will encounter "hot short" metal which will not flow readily under the flame.

The chemical and physical properties of the steel must be maintained at a high degree of uniformity since any appreciable variation will have a great effect upon the welding qualities of the material, as for instance, a high carbon steel will become burnt if subjected to the heat required for low carbon and a light gauge tube will melt through under the action of a flame, which is proper for heavy gauge stock.

We have considered at some length the types of welding machines and their application in the industry as well as look into the material we are to work with.

Material Used

Let us now start with our raw material and follow it step by step to the finished stages in one of the processes we have been discussing. The most important application of steam-welding, as well as the most interesting in my opinion is the tube-welding, as well as process. Here, our stock is received from the mills either in coils of variable length depending on the gauge and width of stock, or in flat strips of suitable length for handling in shipping, or else in mill sheets. If the stock is received in sheets these must be cut into strips of desired width by passing through slitting rolls prior to the forming operation. Strip stock is usually received from the mills slit to width, but if not, this stock too, should be trimmed to desired width to remove the selvage or round natural edge which will not produce a uniform high-grade weld.

This stock of proper width is run through a continuous rolling machine consisting of several pairs of gear driven companion rolls of such design as to gradually form the stock from a flat strip to an open seam tube. These flat strips which have been cut to proper length prior to entering the forming rolls pass through the tube forming machine at a speed of from 50 to 250 feet per minute depending on the size and gauge of the stock and come out uniform in cross section and with a straight seam, both of which conditions are essential to good weldin.

The open seam tube is placed in a trough in front of a seam-welding machine equipped with a pair of vertical rolls which propel the tube forward at a comparatively slow speed under the stationary welding torch and through pressure rolls where the weld is completed. A stationary guide blade riding between the edges of the tube prevents the seam from twisting and getting out of line with the welding flame. After leaving the pressure rolls, the hot tubing passes into a pair of sizing rolls which restores it to proper cross section Here water is poured on the tubing to cool it prior to the straightening operation which takes place in the final pair of rolls.

Our tubing is now welded and straightenend and sufficiently true in diameter and smooth in finish for many purposes for which it can now be cut to length and fabricated or shipped as straight tube. If further refinement of finish is desired, the tubing can be polished on an emery coated felt or canvas wheel to remove the slight excess of metal left along the seam and then be sized in rotary swaging machine.

A single size of welded tubing can be drawn to any number of smaller sizes and various shapes by first annealing to refine the grain of the steel and then passing thru dies or rolls on a drawbench. The weld that has been produced in this process in a combination of steel casting and compression weld and unless refined, will not have as good physical properties as the original metal. As the abutting edges of the tube come under the influence of the welding flame, the upper surface of the stock is heated to the fusing point and a puddle of molten metal is formed while the lower portion not in direct contact with the flame has received sufficient heat by the conduction through the metal to become plastic, or, in other words, is at a welding heat. The pressure exerted by the pressure rolls completes the weld by forcing together the edges of the stock now plastic and the result is a compression weld on the underside and a fusion weld on top. When you consider that the majority of gas-welded tubing is manufactured from stock 1-32 in. 1-16 in. in thickness it is evident that very close regulation of the heat is necessary to produce a perfect weld.

If a single jet torch is used for welding it becomes necessary to raise the temperature of the metal 2600 deg. F., or in other words, from room temperature to the melting point of steel, in a fractional part of a second while on the other hand if several jets are acting upon the stock as in the case of the multiple-jet torch, the metal will be preheated gradually up to the proper temperature and the lower section of the steel will be allowed sufficient time to reach a plastic stage.

On a given gauge of tubing the faster the welding speed desired the greater the distance between jets to obtain maximum economy in the welding flame.

High Speed Welding

The tendency toward high speed welding in the past few years has resulted in much bad welding due to the fact that the necessary concentration of the heat was so great to obtain proper penetration that the upper surface of the steel was burned by the time the lower section had reached a welding heat or else the upper section was properly fused and the lower portion never reached a welding heat and resulted in what is known in shop practice as a "cold weld" or "sweat weld."

A machine welding torch requires for its operation a larger volume of oxygen in relation to acetylene than is the case with a hand welding torch, due to the inability of the flame to derive as large a percentage of its oxygen from the air while burning in a confined space between dies or rolls where there is not a free cultivation of air.

The chemical reaction for the complete combustion of acetylene is as follows:

$$2(C_2H_2)+5(O_2)= 4(CO_2)+2(H_2O)$$

Here we see that it requires 2½ parts of oxygen to one of acetylene for the complete reaction. But, in the welding flame this reaction takes place in three stages:

No. 1. $2(C_2H_2)+2(O_2)= 2(H_2)+4(CO)$

No. 2. $2(H_2)+4(CO)+2(O_2)= 2(H_2)+4(CO_2)$

No. 3. $2(H_2)+4(CO_2)+(O_2)= 2(H_2O)+4(CO_2)$

In a hand torch one part of oxygen is mixed with one part of acetylene in the torch and reaction No. 1 takes place at the tip of the first cone of the welding flame.

Reactions No. 2 and No. 3 should obtain oxygen from the surrounding air as the torch is moved about in the hand welding operation.

However, since the machine torch is either stationary or operating in a confined space where air curents are more or less obstructed it is necessary to furnish -¼ to 2 parts of oxygen to one part of acetylene for proper torch operation.

This excess of oxygen is detrimental to the weld as the free oxygen will strike against the heated metal and cause oxidation. This can be remedied

Continued on page 52

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

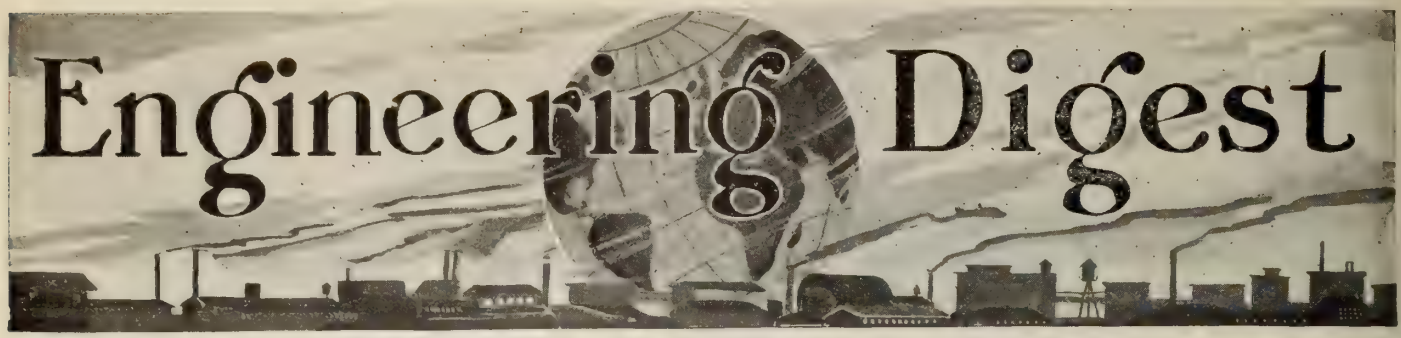
The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

We promised to give two scales to the two winners of this contest, but unfortunately for readers, there is only one contestant with a correct list. This is from Lorne M. McKenzie, of D. McKenzie Machinery Co., Guelph, Ont. A scale is being forwarded to him today.

CONTEST FOR SEPTEMBER 8th ISSUE



Contestants are required to write us, stating to which advertisements we refer in this number.

1—Something a best man appreciates.
2—Done just right in half a mo'.
3—Turning mill to a 35-foot swing.
4—Seven decades to solve a problem.
5—A brush with strength of a pyramid.
6—A canine clamp made to stand up.
7—A Spring Maid (made) over 50 years.
8—An appliance for enlarging.
9—Locked joints, strength about the dash but no waste.
10—Specialty 20 years old and still going strong.
11—A 35-inch swing over a bed.
12—Something twice as large, bigger and better than ever before.

These are Correct Answers for List from August 18th Issue:

1—Bilton Machine Tool Co.
2—Pratt & Whitney Co.
3—L. S. Starrett Co.
4—The Heald Machine Co.
5—E. W. Bliss Co.
6—S. F. Bowser Co.
7—The Bristol Co.
8—Wright Mfg. Co.
9—Algoma Steel Corporation.
10—Ford-Smith Machine Co.
11—S.K.F. Co.
12—Canadian Fairbanks Morse Co.

Closing Date for This Contest is Sept. 29th

Accounting For Scrap

THE subject of spoiled material, in other words "Scrap," has, and always will be a live one. We hate to admit that we have a considerable amount of spoiled work on our hands, yet the pile of wasted effort shows itself month by month. C. B. Williams tackles the subject boldly in the official publication of the National Association of Cost Accountants. Speaking on a sensible method of accounting for scrap he says:

"Scrap credits are frequently made to general overhead or to miscellaneous income account. The unsoundness of this procedure is at once apparent if it be remembered that scrap is an item relating entirely to material cost and cannot, by any line of reasoning, be associated with the items making up general overhead. Of course, the ideal method would be to credit the scrap value directly to individual orders or items, but this procedure is often impossible. In each case investigated, an attempt to deduct scrap from raw material costs has proved itself to be well worth the initial trouble. The problem which presented itself in each case was the same, namely:

"The production of scrap of high raw-material value. The impossibility, under the conditions, of crediting the orders with actual values produced. How to handle the values in such a way as to distribute them as equitably as possible to the several items entitled to these credits. The solution which to my mind is the most feasible and at the same time the most logical, may be summarized as follows:

"Establish a standard unit raw material quantity charge for each item, and also a standard salvage credit if this be possible. Charge each order or item with the total raw material requisitioned against it.

"Credit each order or item with its proportion of salvaged material as determined from the standard unit quantity charge or credit, charging salvage account with the amount of the credit adjustment. Salvage value must be determined in each case according to the use to be made of the salvaged material.

"Credit salvage account and charge, according to requisitions, the order or item using the scrap as raw material, pricing it at the same figure as that at which salvage account is charged.

"The step in this solution which has been the most difficult to apply in practice, and which, therefore, is liable to cause the greatest hesitancy, is the fixing of standard unit quantities. After this first and most difficult part of the problem has been worked out, the succeeding steps can be easily followed because they are largely a matter of adapting routine that is likely to be already present in any efficient cost system, to the special needs of a particular problem."

Application of Compressed Air

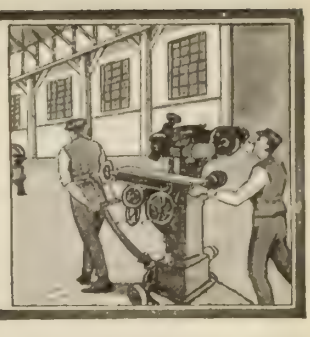
A RATHER humerous anecdote is related concerning what is claimed to be the first time that compressed air was employed to eject work from a power press. A young fellow applied for a job as a die-setter in a power press shop of considerable size, and was engaged on the strength of the glowing capabilities he claimed for himself. The first task given him was to set up and try out a die for stamping a simple circular blank of very bright metal, and he was given the choice of two presses for the purpose. Both presses were small and of equal capacity, but one was of the straight-sided type, while the other was an inclinable press. He chose the latter for the work. The boss kept his eye on the young die-setter because, from a previous inspection of the construction of the die, he knew that the stamping would not lift out and slide away from the press of its own accord, even though the machine was inclined at a generous angle.

When the die had been set up and was tried out, continues the writer in a recent issue of "Machinery" the result was not as the die-setter expected, but, of course, as the boss had anticipated—the work would not slide off the die. The young fellow seemed puzzled for a minute; then his worried look changed to one of hope and understanding. He left the press for a few minutes and returned with a hand bellows. This he gave to his helper and stationed the latter in a sitting position on the floor and under the press. The helper was then instructed to place the nozzle in a vent in the bottom of the die and to squeeze hard immediately after each tripping of the machine. The helper followed the instructions faithfully and the stampings kept flowing out of the die and rolling from the press after each operation. Thus, the young genius not only made good on his new job, but also instituted the first compressed-air device for the removal of small stampings from a press, even though it was operated by a "human knock-out."

Machining of Aluminium

ALUMINIUM enters so largely into machine construction today that it is necessary to study closely its characteristics from the machining standpoint. Some excellent advice on the subject is given in a handbook published by the British Aluminium Company. This company has investigated thoroughly alloys with a view to determining their machining qualities and the most suitable treatment.

For turning, drilling or milling a high speed is found best, and the tools should have acute cutting edges, preferably finished on an oil stone. or the clearance angle of a lathe tool 15° to 20° is advised, and with the smaller angle a 5° top rake may be given. This top rake should be modified according to the rigidity of the work, as with light work there is a tendency for the tool to dig into the metal. Cutting speeds of about 600 ft. per minute are permissible, and a heavier and faster feed than with brass may be employed.



For screwing purposes they use a special alloy, and recommend the use of a paraffin as a lubricant instead of turpentine, which tends to leave a resinous deposit that may cause the screw to bind. In milling, the best results are said to be obtained by the use of a built-up tool, the cutters being ground with sharp corners. The cutters should only cut at the extreme points and not have a scraping action as with brass. Cutter speeds of 500 to 600 ft. per minute are commonly used.

When grinding aluminium the wheel should first have a piece of paraffin wax held against it to fill up the pores. A wheel so treated will not cause the metal to adhere to it and will not require to be so frequently dressed. Any kind of grinding wheel may be used (emery, corundum, carborundum, etc.) but crystolon wheels are said to give the best results.

It is advised that filing be done with a single-cut file, as cross-cut files are readily clogged and require frequent cleaning with a wire brush. A quicker method of cleaning is to immerse the file in a strong solution of caustic soda, which rapidly dissolves the aluminium. Files so treated must afterwards be washed in water and dried in sawdust or they will quickly rust. For finish filing, the file should be kept wet with paraffin or even with water.

DEVELOPMENTS IN SHOP EQUIPMENT

REVOLVING CAR DUMPER

The Wellman-Seaver Morgan Co. Cleveland, Ohio, have marketed a revolving car dumper. This apparatus has been developed to meet the demand for a low capacity machine of simple construction, adaptable to plants where the first cost of installation is a governing factor, but here high efficiency, low operating cost and minimum labor are required.

All sizes and capacities of cars are handled by this machine. The cars may be short or long, high or low, wide or narrow, the clamping arrangement automatically adjusts to the size of the car the machine is handling. It is only necessary to place the car in the machine and turn the control lever and the car is inverted, discharging the contents into the bin underneath. After dumping, the car is returned to its original position by simply turning the control lever in the opposite direction. With the single exception of the revolving operation, all of the functions are entirely automatic, and that operation is controlled by a single lever.

The machine consists of a car-loading cradle which is supported at either end by equalizing rollers upon which it revolves. These rollers are carried in structural steel bases securely bolted to the foundation. The end frames of the cradle are in the form of circular girders which are partially surrounded by gear segments. Rotation is accomplished by two pinions meshing with the gear segments and driven by a single motor supported on the main foundation at the rear of the cradle. Two sets of car clamps are used to hold the car in the cradle while dumping these clamps are normally held in their upper position when the cradle is ready to receive a load or discharge an empty car, and in this position ample clearance is allowed so that the largest car or even a yard locomotive can enter the cradle.

The machine is operated from a cab at one end of the cradle, elevated to such a point that the operator has a clear view of his work at all times.

It is to be noted that only a single motor is required for the operation of the machine. There are no electrical connections on the cradle and no complicated interlocks to get out of order. It is impossible for the operator to make a wrong move which would cause a serious accident, as he has only one lever to operate. By varying the size of the motor, any practical speed of operation may be secured. For instance a capacity of 15 cars per hour requires a 40 h.p. motor. If a smaller number of cars per hour is required, a correspondingly smaller motor may be used. Either direct or alternating current may be used.

VERTICAL DRAWING BOARD

The Simplex Tool and Instrument Co., Camden, N.J., have added to their line of drafting outfits, a style C vertical drawing board. The board is equipped with a Simplex drafting machine. It is regularly made 42 inches in width and to any length desired. It is intended for use in making large drawings such as require a draftsman to be in a standing position while developing them. The board is counterweighted, and slides up and down on a pedestal, this being especially advantageous when a draftsman wishes to work at the top of a large drawing. The drafting machine is operated entirely by the left hand, thus leaving the draftsman's right hand free to use a pencil. The board can also be supplisd with a frame to enable it to be attached to a wall, instead of being placed on the floor.

CENTERING MACHINE

The Hendey Machine Co., Torrington, Conn., has developed and marketed a double head centering machine which is intended chiefly for centering both ends of bars simultaneously. Instead of the usual belts driving to the spindles from an overhead drum, a single belt drives a countershaft running on ball bearings and supported on brackets on the rear of the bed. From the countershaft the power is transmitted to the spindles by means of silent chains. The spindles are fitted with spring collets to hold the centering tools. The work-holding jaws are operated in unison through the medium of bevel gears on a splined shaft, and it is said that the machine can be operated by a 1-2 h.p. motor.

Danger of Government Work

IN another portion of the present issue, we publish a letter received from one of our regular contributors. It touches upon the "treatment of undesirable Workers," and to our mind presents the matter in a rather unfair light. The writer, Mr. John Homewood, evidently has the impression that employers in general are dead on the employee who does work for himself in the firm's time, or to use the shop expression "does a lot of government work."

No one will question for a moment the fact that anyone doing "government work" is nothing short of a thief. This may be a blunt way of putting it, but the truth is often unpleasant. When a man takes his employer's money, he is supposed to work for the latter and not for himself. Any other line of conduct is dishonest. The fact that hundreds of mechanics do little jobs for themselves in the firm's time does not lessen the evil. Some meet this argument with the wail that masters make enough out of them to stand this loss, and that the rate of wage they receive is less than they are worth. In such a case the only remedy is to demand what you're worth and prove you are worth it. In the event of a refusal bide your time then make a move to a firm that can appreciate your work. The evil of "government work" cannot hide behind any wall of excuses. The fact remains that anyone doing work for himself in someone else's time is dishonest, much as he may try to disguise the fact.

It is only very rarely that such an incident as Mr. Homewood cites occurs. The average employer does not take the trouble to hound a man after he has been discharged. Usually he refuses to give him a recommendation and with good cause. Suppose a worker made a practice of doing work for himself. Should the employer give such a man a good character only to wish him on to some other employer? The writer of this editorial has done "government work", been caught at it, then forgiven. Not once, but many times, so that he speaks from experience. A superintendent who fires a man for such a cause, does so, not because of the deed, but for some other deeper reason. The worker may be a very poor mechanic, or perhaps one who is always late for work, etc. A good worker seldom gets discharged for such a complaint, but then a first class worker is too busy producing to steal the employer's time. In fairness to Mr. Homewood we have published his letter verbatim but we cannot see that he has proved his case. The only way to stamp out this evil is for the workers themselves to discourage any attempts at it.

The U. S. Shipping Board

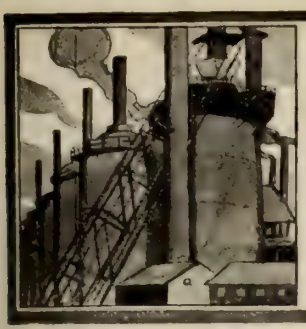
AN American contemporary has come out with a bold plan for straightening out the tangle into which the U. S. Shipping Board fleet has got itself. This is a simple, but withal heroic remedy. The idea is to sell the ships if possible, and if not, sink them. This is perhaps not so wild a suggestion as it would appear at first sight. The fleet as it stands today is costing the U. S. taxpayer millions of dollars annually, for which there is not the slightest prospect of any return. The appointment of three practical shipping men as vice-presidents in charge of actual operation is a good move, but good as these men may be they cannot perform miracles. The whole of the wooden tonnage represents a hopeless loss, as these ships are utterly impossible from any commercial standpoint. From the value of the steel fleets, millions have been or are about to be written off, which will enable them to be offered at a lower price but there are many of them which are unsuitable in size and design for world trade. Owing to the penalty of high wages and high operating costs those that can be kept running are so kept at a loss in every voyage, while from the standpoint of efficiency in operation they are notoriously lacking. The real reason behind the refusal of the Egyptian cotton exporters to charter American ships at a lower figure than they could get British ships at, was due to this inefficiency.

The contemporary in question gives some appaling figures as to the cost of the fleet. The wooden ships are costing $135,000 per month to keep in idleness, while the recent losses of the whole fleet are put by President Lasker of the Board at $300,000,000 per annum, and to keep the Board alive till the end of the year will need a sum of $125,000,000. The losses according to the board's books in operating the fleet amount to $10,000,000 monthly, while repairs consume the neat little sum of $2,000,000 per month.

On the face of these figures the suggestion that the ships be sunk if no other way presents itself of getting rid of them is on the whole not a bad one, and from the point of view of private shipping interests, an excellent one. We are afraid that the suggestion carries little prospect of fruition. The U. S. taxpayer is not yet fully alive to the cost of his bid for sea supremacy.

* * * * *

A Foolish Action



A FEW days ago an onlooker at one of the exhibits in the Machinery Hall at the Toronto exhibition almost ruined a first class turret lathe through his search after knowledge.

The operator at this particular booth was showing to a crowd of interested spectators the lathe's productive capabilities. Naturally, he was very much on the job and had no time to pay attention to the crowd's actions.

Suddenly, an inquisitive onlooker noticed a pretty looking lever which did not seem to be in use. To satisfy his whim he leaned over the railing and pressed the lever to see what would happen.

Whoever he was he must have been quite satisfied for it was the quick traverse lever which he had operated. Luckily, the machine was of rugged design, otherwise the danger would have been very great. It would be pleasing indeed is the party responsible were to read this editorial. Unfortunately this is very unlikely for no real mechanic would have done such a foolish action. Evidently some irresponsible youth had wormed his way through, pushed the lever, and caused the trouble. Let us hope this solution is correct, for we would hate to think a grown-up man would be guilty of such foolhardiness.

From our point of view, a man caught in such an action deserves to be kicked, and kicked hard. We will not stipulate where, but readers can use their own judgment. Anyone viewing such an exhibit should adopt the slogan "Hands off,' and should they see anyone forgetting the motto, warn them first, and if that does not work then use our former advice making the action of the foot swift and decided. Exhibitors pay their demonstrators to operate the machines, and they require no outside help (?)

MARKET DEVELOPMENTS

Business Outlook Is Much Brighter This Week

Machine Tool Trade Has Picked Up Considerably—Orders Are Worth While And Deliveries Good—Small Tools Are About The Same As Usual—Steel Market is Making Headway.

'BUSINESS is improving.' This seems to be the thought uppermost in everybody's mind at present. The machine tool trade occupies premier position in this respect. One dealer claims that last month was the best he had witnessed this year and that he expected the improvement to continue. The orders secured were of such size as to be considered well worth while.

This fact brings out an interesting situation namely, that when a would be purchaser is really anxious for equipment, yet cannot make a quick payment, he can sometimes secure from the manufacturers a reasonable extension, always providing, of course, that his rating is what it should be.

The steel market also shows an upward tendency. Sheets, tubes, and reinforcing materials are all going strong. There is a specially good demand for the latter as building is picking up considerably in some quarters.

The small tool market is about the same as usual, and the least said about the scrap market the better. Stocks are still high so that dealers do not care to buy any further material. Pig iron prices continue to stiffen, and it looks as if this will continue as time goes on.

MARKET IN PITTSBURGH IS BETTER PIG IRON CONTINUES TO HOLD ITS OWN

Special to CANADIAN MACHINERY.

PITTSBURGH, September 8.—After the little backset a week or two ago the improvement in the demand in the steel mills is in swing again. The turn in the tide occured about the middle of July, but the improvement is more impressive by the time it has lasted than by its amount, for even now the demand represents only about 30 per cent of the mill capacity. At the middle of July, however, the mills were scarcely operating at 20 per cent of capacity.

Improvement from week to week has been very slight, only barely perceptible, but longer range comparisons make more pronounced showings. One of the large steel companies finds that its bookings in August were more than 50 per cent greater than its bookings in July, and there are several that show increases between 30 and 40 per cent. There is probably not a single case of any steel producer or steel finisher of any size not having at least a little better business in August than July.

Nearly all the improvement to date, in demand on the steel mills, is traceable to exhaustion or partial exhaustion of stocks in the hands of distributors or manufacturing consumers. According to all accounts there is some improvement in general business, and that of course is a good thing in its way, but the outstanding feature of the steel situation recently was that the demand on the steel mills was far below what it should be in view of the condition of general business. That was due simply to the existence of stocks, as all holders of steel or of things made of steel desired to liquidate. Some had abnormal stocks, but the general policy was not to reduce stocks to normal but to reduce them to nothing. Such a policy is likely to be pursued too far and it is quite possible that in a few weeks there will be a disposition to build stocks up towards normal. If buyers of steel were afraid that steel prices were artificial and would break so as to cause losses there is good ground now for them to abandon such fears, for it is quite certain that steel prices now are at the bottom or are so near the bottom that no material loss can be sustained. It is true that steel prices are up, on an average, about 71 per cent over their minimum in December, 1914, but the prices at that time were quite unprofitable, and the fundamental items of cost have advanced fully as much. Prices cannot come down much from their present level, if at all, except by these fundamental items going down, as by a general reduction in freight rates and by wages coming down farther, and such things will require time. At the top level, the common labor rate was 46 cents an hour, with time and a half for hours in excess of eight, while now the standard rate is 30 cents, without overtime. That is, a man used to be paid, for 12 hours' time, 14 times 46 cents, while now for 12 hours time he is paid 12 times 30 cents.

In the case of bars, shapes and plates, the regular or open market (subject to occasional shading) is 1.75c, which is 67 per cent above the open market in December, 1914, which was 1.05c., subject to shading in some cases to 1.00c. The 67 per cent is $14 a ton. Thus the market cannot "break,' the only change possible being one of say $1. or $2 a ton or something like that, altogether insignificant compared with the many dollars a ton by which the market has receded up to this time.

In the case of sheets, which recently had quite a drop, there is a possibility that there will soon be an advance from the present level of 2.75c. for black and 3.75c. for galvanized, as these prices are lower, relative to cost, than are prices of other steel products.

Shapes and plates are quoted rather openly now at 1.75c. against 1.80c. a week or two ago, and there is a little shading on desirable orders. Bars are rather stiff at 1.75c., with little shading. Late in July the open market declined to 7.75c. on bars and 1.85c. on plates and shapes, but some mills were shading freely on attractive orders, and it is a question whether the extreme price is any lower now than it was then. In other words, the market is steadier, with less of a spread between carloads and large lots.

Buying of steel products, as for several weeks past, is widespread, there being many orders, coming from all parts of the cauntry and almost all classes of trade, the orders all being small. The buying is of course of strictly hand to mouth character, no one taking any more steel than can be

liquidated at once. Among manufacturing consumers, the agricultural implement trade is conspicuous by its absence, there being scarcely any other line of consumption that does not show a little demand. The electrical goods market is rather quiet. There is quite a fair demand for sheets for eave trough and conductor pipe, and there is a very fair demand for all classes of steel from the automobile trade. Jobbing demand is decidedly fair, particularly in the south and southwest.

Railroad demand is light all along the line, except that there is a heavy demand for galvanized sheets for car roofs. A few releases have been received in the past fortnight, for shipments of rails on contracts made for the present year. Some of the rail tonnage billed for this year will undoubtedly be held over, partly because the railroads are short of funds and partly, perhaps, on account of hopes that the price of rails will be reduced.

Pig Iron

The stiffening in pig iron prices continues. The Chicago maret has gone up a total of $3 from its recent low point, Buffalo being up a dollar or so. The valley market on foundry is up another 50 cents, or to $20.50, valley, against $19.50 at the low point.

One way of putting it is that pig iron is advancing because freight rates on ore, coke and limestone have not been reduced and may not be reduced for months. Months ago nearly all the merchant furnaces went out of blast, with stocks, and of course they wished to liquidate the stocks as costs were expected to decrease. By and by prices had gone below the current cost of production, but perhaps not below what would be the cost of production when freight rates should be reduced. The condition now, however, is that the stocks are pretty well liquidated and the freight rates are not down. A furnace might sell its stocks at any price, but it would not blow in to make pig iron at a loss.

Connellsville coke prices are plainly defined and it is made clear that reports in circulation in some quarters for some weeks past, as to low prices that could be done, were without foundation. While $2.75 was reported possible on furnace coke, a contract has been made at $3.10, the American Rolling Mill Company buying 9,000 tons a month, September, October and November, from the Hillman Coal and Coke Company, and this is considered the market level. For one month the price might be $3.00, but for delivery beginning October 1 and running through December the price would probably be $3.25. Spot foundry coke remains quotable at $4.00 to $4.50.

Gotfredson Joyce Corporation, have opened a sales office at 144 Bleury St., Montreal, which will be under the management of Mr. G. L. Ellis, who was for several years connected with the White Company.

POINTS IN WEEK'S MARKETING NOTES

Salesmanship is now a big factor. Firms are finding the competition very keen, therefore they must use capable salesmen to dispose of their goods.

Although the war finished almost three years ago, many firms are still wiping off losses. This causes price lists to be almost non-existent, as stocks are being disposed of for whatever the market will bring.

The sale of small tools and high speed steel in the Montreal field is of the hand to mouth variety. Shops are only purchasing what they actually require.

Although sheets in the Pittsburgh Market had a drop recently, there is a possibility of their advancing from their present level.

Shapes and plates are being quoted at $1.75c against 1.80c a week or two ago. Even at these prices, shading is being done where the order is large enough.

Buying of steel products is of the hand to mouth variety. Railroad demand is light, and some hope is expressed that the price of rails will be reduced.

Sheets and Tubes are moving very nicely and there is a good demand for reinforcing material. Prices on boiler tubes remains the same.

The machine tool business has picked up splendidly this last month. According to one dealer August was the best period this year. The orders secured were of good proportions, and the deliveries with one exception, were very good, the reason for the delay in the one case being the fact that the machine was special.

TORONTO MARKET SHOWS IMPROVEMENT

Market Can be Truthfully Said to be on Its Feet Again. Confidence is Evident and Machine Tools Are Active

TORONTO, Sept 9th. There is a decided upward trend in the market at present. No matter what line you talk to the answer is the same, viz, "Business is picking up."

The machine tool business especially has come to life. One dealer mentioned to Canadian Machinery, that August had been the best month of the year, so far as he was concerned. People are at last realizing that machine tools cannot be bought for next to nothing, therefore they are purchasing the new equipment they so badly need. One machine alone, which was sold in August, cost over $23,000, and this was only one item on the order. More detail on this particular tool in next weeks issue.

Manufacturers of machine tools are being very decent these days regarding financial arrangements. According to one dealer, a prospect of his wanted some machinery pretty badly, but could not stir up the cash just at the moment. It looked as if the business would not go through for the banks refused to loan money for the purchase. The dealer naturally was loath to lose such an order so he wrote the firm he was representing explaining the situation clearly. Back came a prompt reply offering the would be purchaser such splendid inducements that he immediately closed the deal. This shows clearly that now is a good time for buyer, maker, and dealer to get together.

Collections in some quarters seems to be rather poor. One dealer reports that he has been forced to take back a few tools at a loss, while another states his collections are improving. The chief point is people are buying, and as a general rule they are in a good position to pay.

The Steel Market

This section of the market is also picking up. One concern told Canadian Machinery that last month was the best since the break. Over 1000 car loads were shipped last month from this particular firms premises.

Reinforcing material is going strong. One dealer explains the sudden spurt by pointing out that the material bought at present is not so much for new buildings as for those already in course of erection. "Many builders" he said, "are simply buying material as they progress." One party asked us to quote on the material for one floor only, and wanted us to protect him against a decline in prices. I said I would if he in turn protected us against a sudden rise." That finished the argument and the order for the complete building was secured at the current market rate.

Sheets are moving nicely, especially the blue annealed variety. Boiler tubes are also being sold in good quantities, so that no further drop in this commoity is looked for.

Small Tools

The small tool market is much the same as usual. One dealer claims that if he took every month since the first of the year and compared figures they would almost be alike. "We cannot complain" he concluded; for we are doing as well as can be expected."

The scrap market sails along unconcerned. Nothing has happened during the past week. Buying is of the very light variety, and as far as prices are concerned they vary depending on the size of the order. Stocks are still high so that dealers are not in the market except the price asked is very favorable.

PRICE LISTS NON-EXISTENT IN MANY LINES—PIG IRON IS STRONGER

MONTREAL Sept. 8—The slight general improvement shown in general business conditions last week, throughout the Province of Quebec was a source of a great deal of satisfaction to the trade generally. This week's reports show that the improvement has continued. Of course, trade is far below normal in all lines, but a slow steady improvement is an indication of a healthy and permanent move in the right direction. During the war years when business was stimulated to such unnatural and abnormal growth, dealers and manufacturers had to adjust themselves to the conditions as best they could. Everyone had to alter their ideas and methods. The art of salesmanship was not a factor in business. In many lines orders came in unsolicited and each additional one is often an embarrassment.

To-day, with trade as abnormally quiet, as it was previously abnormally good, firms are again participating in competitive selling. Revenues being small it is a great problem to organize a really efficient and representative sales department. Many firms, including dealers and manufacturers, carried heavy stocks previous to the present slump in business. To-day, almost three years after the cessation of the war, and almost one year after the break in general business circles, liquidation is still going on. Such conditions cause price lists in many lines to be non-existent as stocks are being disposed of for whatever the market will bring. Until this liquidation has been completed and new stocks procured, a settled condition cannot be obtained. The railroad situation is one that has a very direct bearing on the machine tool, and iron and steel markets. Not for over twenty years have the purchases of the large railways been of such conservative nature. They are only purchasing in small quantities and then only what they require for immediate use.

Building throughout the large centres is fairly active. This line of work, though far below normal, is one to be reckoned with, and next year's programme promises to be up to, and will perhaps exceed, that of normal years.

Steel Industry

Throughout the States the steel mills are producing but a small percentage of their capacity and this condition, generally speaking, applies to Canada. A nominal tonnage in rails is being produced. Structural steel is in good demand. Most firms have to-day a fair stock of structural shapes and purchases are limited to stock replacement orders only. Bars are in little demand and most jobbers are carrying little or no stock. No British bars are being imported. The small consumption is being taken care of by American and Canadian mills. Sheets and plates are moving out slowly with little tendency toward an increasing volume of business.

Pig iron has shown a slight tendency to strengthen in price. Orders for small to medium lots are reported from many sources. However, the large foundries are doing little or nothing. The foundries in the railway shops are doing nothing to speak of. The small and medium sized foundries in both the city and the rural districts are operating and it is from them that the demand for pig comes. The low price of two weeks ago was considerably below production cost. The low level was caused by some American steel companies entering the field with their surplus of pig iron and cutting prices. Of course, there are many furnaces idle throughout the country and should the demand for pig iron increase it is not likely that these furnaces would "blow in' until the prices had increased to a point where at least production cost is assured. Anticipating a probable shortage some firms have approached the producers for contracts covering several months. This the companies are refusing, and present quotations are for immediate deliveries only. Thus, there is every reason to believe that if the demand continues to improve, the price will increase until there is a fair bargain for the producer.

High Speed Steel and Small Tools.

Sales of small tools and high speed steel are of a "hand to mouth" variety. The volume from week to week changes but little. None of the large shops are operating to any extent and thus the smaller shops are furnishing the demand. Prices are not stable as many dealers still have stocks purchased at prices higher than the present general schedule. Therefore quotations are usually made for each order. There is a great deal of competition in this trade and the manufacturers are working hard to place their goods with the jobbers and dealers.

Business is not showing any improvement in the scrap metal trade. A small amount is being done but for several weeks prices have been at a low level and very little business offering. In the non-ferrous metal market business continues to be very dull. Prices have weakened a little and but a small amount of business is moving.

CHEMICAL MEN DISCUSS PROBLEMS

Prominent British Scientists Discuss Chemical Problems. Interesting Three Day Program.

The Society of Chemical Industry held their Fortieth Annual Meeting in Montreal on August 29, 30 and 31. Many of the leading chemists of Great Britain were in attendance and it is the intention of the visitors to investigate several of the Canadian industries with a view to finding out the application of chemistry to these industries.

According to Sir William Pope, K.B.E., F. R. S., president of the society, the pulp and paper industry is attracting great interest among British chemists. The members visited several of the large pulp and paper factories in the Province of Quebec. The carbide industry and similar works connected with the hydro-electric plants were also a source of great interest to the chemists and they were shown Shawinigan Falls. Grand Mere and other points where there are plants using chemical and electric forces for commercial purposes.

As yet Sir William could not say in what particular way the chemists might be able to aid these industries, but great things were being done by research work and occasionally aid was forthcoming where least expected,

The party left Montreal on Sept. 2nd for New York, where they will attend the annual meeting of the American Chemical Society, but while in Montreal several interesting papers were presented.

BELGIUM PRODUCES AUTOS SUCCESSFULLY

The manufacture of automobiles in Belgium has progressed steadily since the armistice, and several works have been successful in the production of one, three, and five-ton lorries at competitive prices. According to reports no American trucks have entered the country for some months. A number of well-equipped makers at Liege and Brussels are turning out luxury and touring cars. With their first-hand knowledge of the country's special requirements they are able to supply a chassis of very solid construction, capable of withstanding the strain of Belgium's rough roads. Under similar usage certain American chassis are reported to have broken down in a few months.

France, however, still manages to compete in the Belgium market, thanks to her mass production of small 10-14 h.p. cars, which are very popular. The importation of these and of other French makes is increasing to some extent, whilst purchases from other countries are negligible. Owing to the large number of excellent coachbuilders in the country, the Belgian customer prefers to buy a chassis and have a body built for it either in Brussels, Liege, or Antwerp, where the wheels are at the same time fitted with locally made tires.

Belgian manufacturers are obtaining good orders in countries where road surfaces resemble their own, notably the Balkans and northern Africa. Their motor cycles, too, are going overseas in increasing numbers, fairly large sales having recently been made for Poland, Greece, Brazil, China and the Congo. The tire factories in Liege, Brussels, and Ghent are naturally benefiting by this activity in the motor vehicle business.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Grey forge, Pittsburgh	$22 00
Lake Superior, charcoal, Chicago	30 00
Standard low phos., Philadelphia	41 50

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

PRINCIPLES GOVERNING DEVELOPMENT OF CANADA'S EXPORT TRADE

DURING the annual report on export trade conditions, the Commercial Intelligence Dept. quoted several principles governing the development of Canada's export trade which are well worth repeating. They state that at the present time great care and caution should be taken in entering foreign fields. There are in Canada good facilities for obtaining credit information on foreign firms and buyers. Reliable information should be secured before entering into any contract with a foreign firm or individual.

Exporters should not be impatient of results in foreign markets. It is better to remain established in the export trade with no immediate profit, than to drop out and enter at another time. A sound, permanent market is what is required. All contracts must be lived up to. Orders should be punctually filled to the satisfaction of the customer. In many countries Canadians are classed as Britishers and Britishers have the reputation for keeping contracts and being punctual. This is to our advantage and we should live up to it.

The customer should be given what he wants, and not what we think he should have. Shipments should always be up to sample. We must please our customers and not ourselves. Courtesy in correspondence is doubly necessary. While much trade can be secured through export commission houses, and resident agents in foreign countries, it is a much better method to send Canadian travellers abroad. Canadian goods can best be introduced by Canadian salesmen; and whatever means we finally employ for the distribution of our goods abroad, it is a great advantage to have some principal or trusted employee, connected with the firm, who knows conditions in our export markets.

Holding Our Trade

If we are to hold and extend our export trade, it is becoming more and more essential that quotations should be made c.i.f. foreign ports. Agents and buyers from other countries emphasize this. Exporters from other countries follow this practice, and their agent is thus enabled to quote the foreign buyer a laid-down price on short notice. A foreign buyer is generally not in the position to work out freight, insurance and shipping charges from a Canadian port. Many Canadian exporters keep up-to-date price lists of their various commodities laid down in foreign countries, overcoming the fluctuations of exchange rate for a set period, giving the customer the benefit of any improvement between placing of order and due date of payment.

Proper packing, with due consideration to character of goods and special hazards of ocean or difficult overland shipping is an important factor in retaining the goodwill of customers. It is essential, as in domestic business, that the utmost economy in production costs must be obtained.

In many countries Canada is judged by the actions of her citizens doing business there. In every export trade transaction the Canadian exporter has in his keeping not only his own reputation for integrity and fair dealing, but also the reputation of all other Canadians who are doing or who may seek to do business in export markets.

Generally speaking, in the absence of many of the accessories facilitating export trade with which longer established trading nations are equipped, it can scarcely be gainsaid that the most favorable markets for Canadian products remain those countries where English is spoken, trading customs similar, and in some cases preferential treatment accorded to Canadian producers. Next in order should come possibly South America, France, African protectorates and the Far East.

MACHINERY EXHIBITORS WILL GET TOGETHER

"IF THE machine tool dealers and manufacturers, and exhibitors who are interested in Machinery Hall want a better place in which to place their exhibits, then let them get together and go to the president and directors of the National Exhibition and state their case."

Such is the advice given to the machine tool men by J. Murray, one of the directors of the Fair, and a man who has interested himself many times on behalf of securing a better place in which to house the exhibits.

The suggestion made above was put up to a number of the exhibitors in Machinery Hall at Toronto Fair, and seemed to meet with a ready response from all of them. Apparently all the agitation of past years has failed because those doing the agitating and the objecting did it individually. The new move, now proposed, brings with it something in the line of strategy.

The exhibitors, on their part, will be expected to enter into some sort of an understanding with the management of the exhibition. They would probably be required to state definitely what amount of floor space they would be willing to take, so that the directors would have something definite on which to work in the matter of estimating the revenue for the upkeep and depreciation of the new building which might be erected.

Time for a Change

Exhibitors, especially those who place heavy equipment on the floor of Machinery Hall, know only too well what they have been up against this year, and every preceding year, in the attempts to place their exhibits without tearing the building to pieces. There is not even a block and tackle to assist in the work of putting goods along by means of rollers. There is no overhead crane, and there is a very indifferent shipping platform. Brute force and awkwardness are the principal assets in the unloading and placing of exhibits, while the same tactics have to be re-employed when the day comes to take the stuff out again.

Many of those who have been in the building in past years are not to be found there to-day, and the reason for their absence is to be found in the quality of the accommodation provided—or not provided—for them. One firm stated to a representative of this paper that of the exhibits made by them in various cities all over the world, the bill for taking the one to Toronto fair and getting it out again would be the largest ever sent to the home office.

It seems certain that some concerted action will now be taken by the exhibitors themselves, and the agitation in new form for a decent Machinery Hall is under way. It is also understood that it is the intention to greatly enlarge the scope of the exhibits to take in a great variety of machinery, also electrical exhibits, etc.

The scale of wages of the Amalgamated Iron, Steel and Tin Workers, at Hamilton, has been settled for the next year. A general reduction of 4 per cent. is in force.

* * *

Th Sheet Metal Products Co. of Canada have protested against the high tax rate. They claim the rate amounted to 126.3 mil's in Toronto, against 28.3 in Montreal.

LOCOMOTIVE HAS BEEN THEIR SPECIALTY

anadian Locomotive Co. at Kingston Has Always Specialized On Locomotives

The Canadian Locomotive Company, the year ended June 30, 1921, experienced earnings greater than in any ner year in the history of the organiation save one. The net was $827,091.62 against $892,976.32 in 1919, the best ar yet recorded. The earnings in 1920 ell to $367,969.02 owing to labor, troules, which began the previous year and xtended well into that year, and this, ogether with the difficulty of securing aterials owing to the strike and emargoes on American railways, affected e company's output at the time very aterially. The current decline in earngs has, of course, to do with the genal inactivity in trade circles; the railays are not securing traffic in the customed volume, and are not as a nsequence placing as many orders for comotives.

Capacity Was Increased

It was in 1911 that the Canadian comotive Company underwent a reganization and was placed in a more vantageous position to carry on the erations in which for a great many ars it had been engaged. The comny had its beginnings at the Kingston comotive Works, and, as such, was for a great many years the only conct shop in Canada devoted exclusively to the building of locomotives. It was probably under this title that it rned out the first locomotive ever onstructed in Canada. The date of this being 1855. With a few interptions, the company has been workd on locomotives, and on locomotives ly ever since; and at the time of the reganization mentioned it had expandd until it had a yearly output of about locomotives. The lack of facilities for turning out a yet larger number necessitated the refusal on the part of company to accept further orders, and it was this which, in the main, ought about the reorganization. A rious reorganization, for a very simia reason, had also taken place in 1901, the late Hon. William Harty beame connected with the concern. The reorganization—the benefits of which still are being felt—brought Aemilius Jarvis, sr., forward as the conrolling factor, and under his administration the facilities of the company have been greatly extended. The company last year was working on locomotives for the Canadian and Jamaican railways between ten and twelve of which were turned out each month, but during the war, when construction was underway for the British, French and Russian Governments, as high as 80 of the smaller locomotives were built every month. So that the capacity of the works, while much larger than it has ever been, varies according to the type and size of the locomotive under construction.

SHOULD PRICES OF MACHINE TOOLS DROP?

"That machine tools are selling for very much less than they should sell for." "That at no time, even including the war period, did manufacturers receive anything like a proper return on their capital invested:" "That machine tools generally are selling below the cost of production:"—Such is the consensus of opinion of several well known machine tool manufacturers in the United States.

"In machine tools, the price of a ton of pig iron has little bearing on the total price" says one company. By way of illustration they quote the following case:—

Pig iron selling at $25.00 per ton means 6c. per pound to the machine tool manufacturer purchasing his castings, and in relation to the total price of the finished tool, the price of the pig iron represents about 5%; so that a $2.00 change in pig iron would mean perhaps one-tenth of a cent per pound on the tool. Skilled mechanics prior to the war were poorly paid in comparison to other trades. Today they are still receiving less than other trades, and whilst the cost of skilled labor has receded slightly from the high point of 1920, it is about twice what it was prior to the war, but its efficiency is about 80% as compared to pre-war periods. Most machine tool manufacturers find themselves in the position that whatever profit may have been accumulated is invested in drawings and patterns and extra equipment.

"It is difficult to make a comparison between former and present prices," says another firm "because few manufacturers are selling the same tools today that they were selling before the war. More tools have been completely redesigned since the beginning of the war than has probably ever been the case in a like period before. Even in those cases where there was not a complete redesign, features have been added and improvements made, which, while adding to the efficiency and convenience in operation, have also raised the cost of construction.

"The skilled machinist was underpaid previous to the war," they continue, "but at present his wages are much better. To say how far machine tools rose during the war would be very difficult, and it is equally impossible to say they will go back to any percentage of pre-war prices. So far it would look as if a 25% reduction from the peak figures of 1920 would be the limit of drop, but of course such is only a guess on our part, based on certain assumptions as to manufacturing conditions. Even the latter cannot always be depended upon, however."

The A. B. Ormsby Co., Toronto have secured the following contracts: at Kingston, Ont., the furnishing of continuous steel sash for addition to plant for Canadian Locomotive Agency and at Montreal, steel sash for power house for Molson's Brewery.

TRAFFIC AT SOO; DECREASE IS NOTED

The traffic through the Canadian and United States canals at Sault Ste. Marie continues to show decreases, due almost entirely to the great reduction in shipments of ore. Iron ore shows a decrease from July, 1920, of 4,887,009 tons, or over 52 per cent. Wheat shipments were about the same as last year, but other grains show increases of 7,409,149 bushels. Bituminous coal going up shows an increase of 1,192,871 tons, or over 92 per cent. Since the opening of navigation 8,076,824 tons have gone up through the canals, as against 2,842,750 tons for the same period of 1920. The traffic through the Canadian lock does not show much change from last year, except that there were no iron ore nor pulpwood shipments through, and there was quite an increase in barley and oats.

The traffic on the Welland Canal showed considerable increase over last year, namely—520,856 tons, against 362,626. This increase was almost entirely in grains. Corn increased from 3,493 tons in 1920 to 196,652 tons. Oats increased from 306 tons to 15,596 tons; wheat from 40,700 tons to 94,252 tons. The corn was United States corn for export, and about 10,000 tons of the wheat was from the United Staes.

The freight on the St. Lawrence Canal increased from 490,543 tons in 1920 to 615,588 tons in July, 1921. As on the Welland Canal, the main increases were in grain, especially United States corn that is moving via Montreal. Wheat and oats also show considerable increases. Both hard and soft coal show decreases.

The decrease in freight on the Chambly Canal was in pulpwood, 5,481 tons, as against 14,325 tons in July, 1920, and in lumber, 6,478 tons against 12,482 tons.

Mr. T. J. McFadden, Ontario representative of the Diamond State Fibre Company of Canada, Limited, has just completed a two months course in technical work at their Toronto head-quarters and is now back on the road again. Mr. J. Alexander Regan, Quebec, representative of the same company has been getting a few pointers in the technical department at Toronto and Bridgeport during his vacation, and has now returned to his duties in Quebec.

A new process by which sand-iron, or magnetic sand, may be converted into pig iron, and thence into steel, has just been made public by Goro Matsukata and Dr. Azobu Nailo. The discovery, scientists say, will not only revolutionize the steel industry in Japan, but of the world. The process is carried out by means of combining the sand iron with coke, using hot gas flames and making ferro-coke from which iron can easily be taken.

R. S. C. Bothwell has been appointed superintendent of construction at the Canadian Johns-Manville Co., Toronto

EXPANSION IS THE RULE OF THIS SHOP

Some Railroad Orders Are Coming In And Others Are Expected—Taking On More Men Now

Mr. G. B. Frost, president of Smith's Falls Malleable Castings, Limited, reports improving conditions in their particular line of industry. While they have never found it necessary to shut down their main plant, they have been running with a reduced staff of about 75 men. Within the past few days, however, they have increased their force by 15, as the result of some improvement in railway demand. Orders from this source have been considerably below normal. In fact, it would appear that the railways have been starving themselves, apparently awaiting a price adjustment. By October railway business should reveal an absolute necessity for certain lines of equipment and repairs, due to increasing traffic in moving crops.

A report from Brockville indicates a development in this direction. The motive power of that division of the G. T. R. has recently reinstated three drivers who have been acting as firemen, and has taken on four new firemen. The business being handled is not far behind the same period last year. Two hundred and ninety engines are now being handled out of Brockville as compared with three hundred and thirteen this time last year. During the past week or two there has been an increase of forty engines per week over previous periods due largely to movement of grain from Georgian Bay ports and cattle from Western Ontario for export.

PRICES DROP IN AGRICULTURAL GOODS

British Manufacturers Cut Prices Considerably—Fear German Competition Ridiculously Low Prices Quoted

British makers of agricultural machinery have adopted a new scale of prices. According to the "London Times" the move has been made principally with a view to combating foreign competition. Drastic cuts have been made in many cases. Following are the amounts of drop in English currency. Readers can convert these figures for themselves, considering of course the current rate of exchange.

Certain farm tractors are £50 to £60 cheaper than they were in the spring, and others formerly offered at £350 to £400 are now obtainable at well under £300. Ploughs, harrows, and cultivators for horse and tractor use have been reduced 15 per cent; food-preparing machinery, such as chaff-cutters, root graters and pulpers, corn kibbling and grinding mils, etc., are also down 15 per cent, and harvesters are quoted £10 per machine cheaper. Farm engines are another line which show a downward price tendency, and the larger size threshers are quoted at lower figures, possibly owing in some measure to the large number of small and cheaper threshers for the farmer's own use which now is finding a ready market at home and overseas.

German competition seems to be most feared by British manufacturers. Although there is no great tonnage being imported into this country from Germany as yet, such goods as have arrived and also those sent to the British Dominions have been offered at ridiculously low prices, in some instances at figures which do not represent the cost of the raw material to the British manufacturers.

A Serious Omission

In reporting the various exhibits in the Machinery Hall at the Toronto Exhibition, the name of **Mechanical Leather's Toronto**, was left out. This was of course unintentional, in fact the copy was all set up but was evidently lost before use. We therefore take the first possible opportunity to acquaint readers of Canadian Machinery that the above concern are showing a very complete line of belting goods, this including rawhide gears, pinions, cups, mallets, hammers of all kinds, belt lacing, round belting, also many other belting lines. Belt fasteners are included in the exhibit, in fact everything necessary in the line of mechanical leather goods is shown. R. W. Coleman and H. R. Alley will be pleased to meet anyone interested.

Trade Gossip

Sudbury.—The indications are that it will be next June before any steps are taken by the International Nickel Co. at Copper Cliff to increase operations.

The Fireproof Warehousing Co., London, Ont., have plans and will receive tenders for the erection of a warehouse which will cost around $100,000. Those interested should write W. Webster, 717 Richmond St.

The painting and glazing contracts for oxygen plant costing $25,000 for Dominion Oxygen Co., Ltd., 120 Elm St., Montreal, are placed with Brinkworth & Sons, 281 Coloraine St., of the same city.

* * *

A town planning a housing convention will be held in Toronto some time in October. Some 2500 delegates are expected and efforts will be made to have several experts come to deliver papers on this most important subject.

* * *

The Standard Supply Company have opened the sales offices at 390 Notre Dame St. W., Montreal, where they will act as distributors for the Canadian Roofing Mfg. Co., Ltd., Windsor, and for the Hamilton Tar & Ammonia Company, Ltd. The Montreal office is under the management of Mr. E. D. Bellefeuille.

* * *

The rate of exchange in connection with shipments of freight between points in Canada and the United States from September 1 to 15 inclusive, will be 10 7-8 per cent.; the surcharge on international freight shipments will be 7 per cent. The rate of surcharge on international passenger business will be based on 11 per cent. exchange.

* * *

Mr. H. Coplan, Managing director of the Hull Iron & Steel Foundries, is said to have made an important discovery in the steel industry. Some years ago "Chromite" came into being, but now Mr. Coplan has adapted this alloy to the manufacture of grate bars for use in steamships, locomotives, etc. The heat resisting power of the new meta is claimed to be even far beyond the inventor's hopes.

* * *

The Leaside munitions plant at Toronto has been purchased by W. C. Durant the founder of General Motors Ltd It is said that the manufacture of Durant automobiles will be started shortly Present plans call for a manufacturing capacity of 100 finished cars per day It is hoped to have the plant producing by next March. The building program calls for the construction of a three storey assembly plant 130x160 ft. and in present intentions are carried out every important part of the new cars will be made in Canada.

The English Electric Co. of Great Britain, said to be one of the largest manufacturers of electrical equipment and machinery in the British Empire is associated with the English Electric Company of Canada. The Canadian Company is associated with and holds the exclusive manufacturing rights in perpetuity for the English company; having use of all their patents, designs processes, etc. In addition they will secure the benefit of the preferential tariff and the present favorable exchange rate. The entire undertaking of the Canadian Crocker-Wheel Company St. Catharines has been acquired so that all the patents and designs are available.

After Ten Years' Test
He Finds the Geometrics of Greatest Merit

Right on the Lead

The Superintendent of a Trade School says he has used Geometric Die Heads for the past ten years and finds them superior to any other make.
The Geometric Tool Company for twenty-five years has specialized in Screw Cutting Tools that combine closest accuracy with greatest production.

Geometric Style DD Die Head for Hand Operated Turrets

In perfecting a Die Head for certain Automatic Screw Machines, features were developed that made the Die Head quite as desirable for hand-operated turrets. Compensating spring mechanism overcomes any inaccuracy of adjustment of the turret. Chasers compensate automatically for any slight irregularities that may exist.

PRODUCTION WELDING

Continued from page 38

to a large degree by inducing air currents around the welding flame in such a manner as to feed the flame without too great a cooling action.

There are many other combustible gases that are used for welding purposes and I have used acetylene for illustration here since it is most commonly used. The efficiency of the welding process is a subject that few regard very seriously in production work so long as the workmanship turned out is of good quality but when you consider the waste that can occur through improper design of equipment, condition of the welding gases or the low thermal efficiency of the welding flame in practice you will readily see the necessity of extensive tests to determine best conditions for operating.

Tests should be conducted to determine the length of seam welded per unit of gas consumed and also the ratio of oxygen to acetylene under each different condition of operating and from these the best can be adopted. You will find that by having the jets very close together a large percentage of the heat is dissipated by radiation while if the jets are too far apart the conduction of heat away from the seam by the adjacent metal will cut down the thermal efficiency of the flame materially, so it is necesary to strike the proper balance of the number of jets, the spacing of the same and the welding speed for a given condition. If the ratio of oxygen to acetylene indicates an excessive consumption of oxygen it is necesary either to remove the obstructions that are cutting off their air currents or else supply air to the flame by induced draft.

Moisture in the gases will reduce the heat of the flame as well as cause the flame to sputter due to condensation of the moisture in the water-cooled tip, but this can be remedied by passing the gases through suitable driers. Dust and dirt should be removed by passing the gases through filters to prevent the dirt from clogging the passages in torches and regulators.

The gas welded tube industry has in the past five years outdistanced all its rivals in the production of light gauge steel tubing and millions of dollars have been invested in tube welding plants, some of which have a capacity of several million feet per month.

This tubing combines light weight, strength and smooth finish with a relatively low production cost and has found a wide use in the manufacture of automobiles, bicycles, motor-cycles, furniture, munitions, aeroplanes, go-carts, conduits, tools, farm implements, gas engines, conveyers and an almost endless list of articles in the construction of which tubular steel parts are required.

The manufacture of gas welded tubing has advanced in a very few years from a small specialty line to a vast industry serving so extensive a field of manufacture that I would weary you with its description. Manufacturers in the past have offered a spirit of secretiveness regarding gas weld production work and are likened unto the servant in the parable who buried the talents for fear that they would be stolen from him instead of allowing them to increase in value through use, to his own enrichment and the benefit of others.

We pride ourselves in some of the achievements in production welding on steel products but the possibilities for the future in welding the other commercial metals in a similar manner are limited only by the skill and imagination of those conversant with the industry.

Trade Gossip

The Works Committee of Hamilton, Ont., are going to ask their board of control for $26,000 for repairing of old asylum sewer.

* * *

The Wallace Barnes Co., of Bristol, Conn., have started a factory in Hamilton,Canada. They have taken over a modern plant formerly occupied by the National Machinery & Supply Co. of the same city, and in their new abode will manufacture their regular lines of screw machine products, cold rolled spring steel, wire, washers, stampings, springs of all kinds, etc. Their line of products is well known on both sides of the line, so that Canadian manufacturers need hardly be acquainted that the establishment of this firm dates back to 1857, and that at present they have membership in the Rice leaders of the world association.

* * *

The Empire Steel Corporation have announced the following appointments:- George D. Macdougall, latterly general superintendent of the Nova Scotia Steel and Coal Co., as chief engineer of the corporation; A. McColl, for many years secretary of the Nova Scotia Steel Co. and assistant to the president, as general manager of the Nova Scotia Company, including the consolidated properties of the Corporation centred around New Glasgow. These appointments are in continuation of the policy of utilizing the best executive material in the staffs of the consolidated companies, so as to restore former efficiency and give the Corporation the benefit of technical direction by specialists already trained and acquainted with local conditions.

As a result of experiments in Melbourne in the production of the bases for dye from coal tar and its by-products a new firm has been established and a small but well-equipped factory will soon be in operation. It is expected that within twelve months the output will be 150 tons a year and that in two years the whole of Australia's requirements can be met. When in full working order the plant will employ between 250 and 300 persons, in addition to a highly trained staff of chemists and other experts. The concern will be entirely an Australian business, carried on with Australian capital, labor and plant. So far a range of fast colors, comprising 54 different shades, has been proved, but every day this number is being added to. Acid, basic, chrome, alizarine, nigrosine, and other types of dyes are to be made.

To Press Damages Claim

W. C. Reilly, general superintendent of Youngstown Sheet and Tube, has been chosen by the government of Nova Scotia as its representative in arbitration proceedings with the Dominion eel Co., in settlement for steel used in the war involving $9,000,000. During the war the company erected a large plate mill Nova Scotia at the request of the Dominion government and entered into a contract for plates to be used for military purposes. When contract was half completed the armistice was signed and the government suspended specifications. The Company asks for payment of the contract and damages resulting from expenditures in erecting the mill.

Grinding Diameters on Ring Gages to Close Limits

n the Terry Turbine Company of Hartford, Conn., Dumore Grinders are used on jobs where accuracy is of the utmost importance.

The job shown here is a special Gage—diameter .750-in. with plus or minus limits of .0002 in. Because the Dumore grinds to extremely close limits it is just the tool for work of this character. Besides, the ease with which it can be set up for service wherever necessary gives it an advantage over other methods of handling many kinds of work.

Dumore Grinders can be used anywhere, taking their power from the nearest lamp socket; extremely simple and durable, they offer an economical method for accurately finishing work without changing the setting.

See the Dumore at work. Ask a man who uses one. Or have your dealer give you a demonstration.

MINERAL OUTPUT.

The mineral output of Austria in 1920 was 134,400 tons of coal and 2,398,354 tons of lignite, as compared with 90,472 tons of coal and 2,006,773 tons of lignite in 1919. Her imports in 1920 were: Coal, 2,547,880 tons; lignite, 1,192,073 tons; coke, 255,072 tons; briquettes, 1,005 tons; pig iron, 36,972 tons; bars, plates, sheets, and wire, 39,972 tons; other finished iron and steel, 40,552 tons; machinery, 19,615 tons. Among her exports were: Ores (mostly iron ore to Czecho-Slovakia), 126,854 tons; magnesite, 62,530 tons (to Germany, the United States, France and Great Britain); pig iron, 75,812 tons; bars, plates, sheets, and wire, 41,875 tons; other finished iron and steel, 66,947 tons; machinery, 30,834 tons.

POWER FROM WOOD REFUSE

At a recent agricultural exhibition in England, several different British makes of suction gas plant were shown, some of them in operation driving engines. They ranged from 2 to 65 horse power, the largest making gas from saw mill refuse, bark, shavings, or other wood waste, and the smallest using charcoal The big plant takes only two and a half, to three and a half lbs. of wood per brake horse power per hour, according to the quality of the wood refuse, and the little one is mounted on its engine on a wooden truck so that it forms a complete portable power plant.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

MACHINE TOOLS AND METAL WORKING EQUIPMENT

Chas. P. Archibald & Co., Montreal.

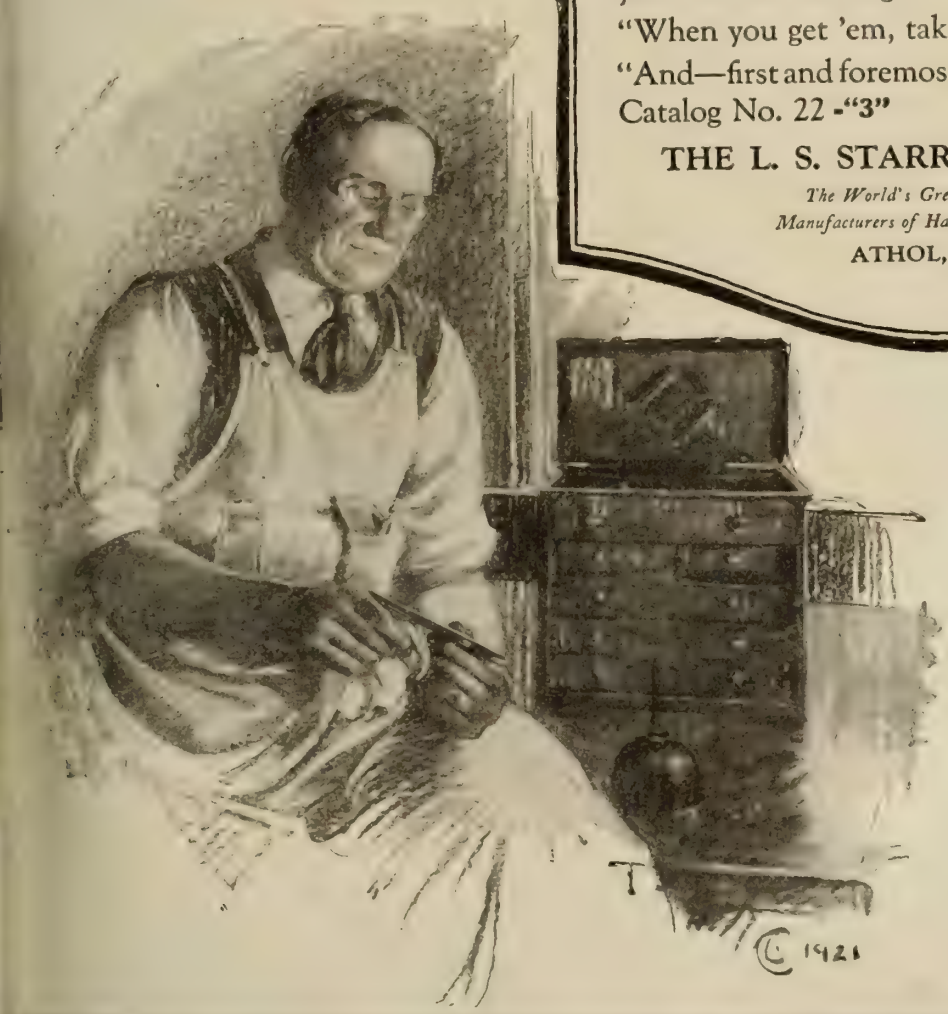
"A Good Machinist respects good Tools.

"He respects you more when he sees that you have a complete kit of Starrett Tools.

"But what I want to bring out now is that he respects the tools themselves. He's *careful* with them. He doesn't throw them around. And he keeps 'em *clean*.

"I wouldn't any more think of using my Starrett micrometers and calipers roughly and carelessly, than I would of touching a match to my money.

"Next time you're near the hardware store check up your Starrett Tool kit, and get those tools you've been needing.



"When you get 'em, take care of 'em.

"And—first and foremost—write for the Starrett Catalog No. 22 -"3"

Brake Carriers Just Right—in 30 seconds

In the plant of one of the large automobile manufacturers, they wanted these Spring Seat and Brake Carriers tapped "just right," and they wanted speed. The carriers were tapped 3¾"—16 U.S.F. and the depth of the thread was 1-½".

While accuracy and speed are generally bad bedfellows, this NAMCO Collapsing Tap tackled the job and produced these carriers "just right" in half a minute—30 seconds.

It's not difficult to get threads just right with NAMCO Self-Opening Dies and Collapsing Taps because they are easy to adjust and when set, they can be depended upon to stay "just right."

One reason for this is their simplicity—there are so few parts. And another reason is the precision of their parts and the way they are put together. Then, too, the chasers are just right in lead, fit and temper. That's important.

Little or big diameters, fine or coarse pitches, there's a NAMCO Thread-cutting Tool that's "just right" for your work. Find out.

It pays to keep a close watch on files.

As soon as a file has lost its original keenness, that file should be discarded at once.

A new file costs less than the labor-time used up by waste effort with a file that is even slightly worn.

These brands give long service before losing their keenness—specify one of them when ordering:

SMALL TOOLS

Pratt & Whitney Adjustable Blade Reamers

These reamers have eccentric relief and can be set to size without regrinding. They are unexcelled for design and simplicity and ease of adjustment.

The eccentrically relieved blades are stronger than others, do not chatter, and produce a smoother hole. The hand, shell and fluted chucking reamers have interchangeable nuts, screws and wrenches. The bottom of a hole can readily be faced.

By a simple adjustment of the blades the reamer can easily be set to size, without regrinding.

Prompt service is assured at our nearest store, where P. & W. Small Tools are carried in stock for immediate delivery. Place your order there to-day.

Your Costs -- Our Skill

There is a vast gulf between the work of the artist who penned this machine and that of a skilled machinist who built it. Yet, both are trained—specialists.

The men who build GRIDLEY Automatic Turret Lathes have a training born in the old school of New England craftsmanship. Like the artist they have mastered the art of machine tool building and take a personal pride in their assembled product.

GRIDLEY Fully-Automatic Turret Lathes have a reputation for giving every effort to their owner—and this means all in speed, accuracy and low cost per piece that reasonably can be expected from a high grade machine. There's one for your work. Accurancy guaranteed, find out how many per hour.

THE JOHNSON FRICTION CLUTCH

It's a Johnson Lineshaft Drive

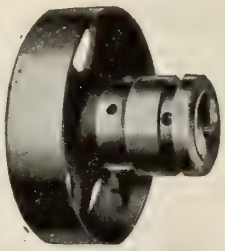
A battery of twelve light presses, all on a bench about 30 x 5, driven from one lineshaft with Johnson Clutches controlling the machines.

COMPARE IT FOR FIRST COST

Twelve Clutches against twelve complete counter shafts, or twelve individual motors.

COMPARE IT FOR EFFICIENCY.

Quick, smooth control against the sluggish tight and loose pulley. Or one motor consuming current instead of twelve.



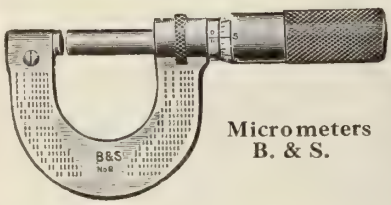
COMPARE IT FOR SERVICE.

You know the failing of belts—the continual attention they require, especially when they are shifted. If you don't know Johnson Clutch Service, just give it a trial.

Illustration by courtesy of The New Departure Manufacturing Co., showing bench presses in operation at their Elmwood Plant.

FRICTION CONTROL MEANS BETTER MACHINERY

We specialize in applying the proper type of friction clutch on any sort of an installation. Standard clutches available from stock, and special models developed to suit conditions.



Write for our booklet

"Clutches As Applied to Machine Building." and our Yellow Catalog.

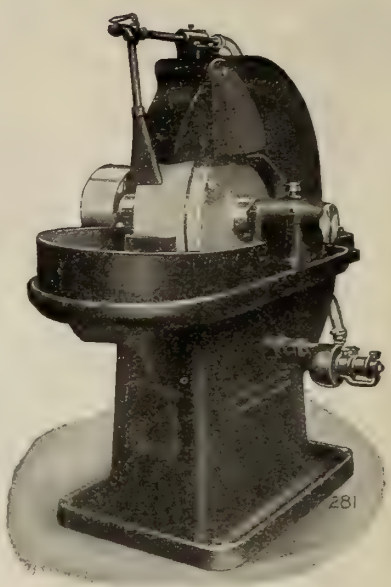
For Either Tools or Production

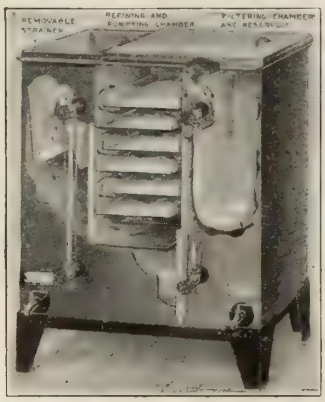
FORD-SMITH



is the right grinder. Why? Because no matter how **different** the purpose, every Ford-Smith Grinder is alike in the fact that its capabilities include quality work, fast work and long life—all at a moderate cost.

Built in the following sizes:—
12, 18, 20, 24, 26, and 30 inches.
Thoroughly tested before leaving the factory.

By using the Disc Grinder with Ring Wheel Chuck for production shown at the left, unskilled help can turn out work in less time than on a milling machine, planer, lathe or special machine tool.



The Wet Tool Grinder at the right is a positive assurance of "bigger output." Its purpose is to keep tools sharp and not lose any time doing it.

Always plenty of belt power and rigidity with this type. In the following sizes:—
12, 16, 20, 24, 30 and 36 inches.

The Ford-Smith Machine Co., Limited

The Life Blood of the Factory

Dirty, gritty lubricating oil will junk your machinery long before its time. *Friction is production's worst enemy,* and the wear and tear caused by dirt and grit in oil slowly but surely wears out expensive bearings and other machinery parts.

Clean oil prolongs the life of machinery. Bowser Lubricating and Filtering Systems assure clean filtered oil on all bearings and restore the oil to its original lubricating quality. Try the Bowser Perfected Process of Seepage Filtration.

Installation takes a minimum of floor space.

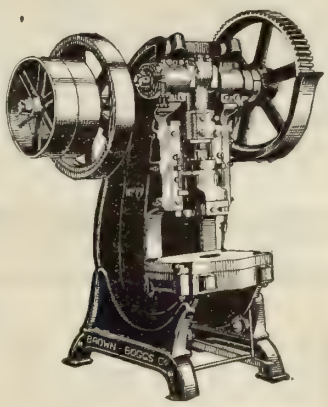
Builders of Volume Production



No. 15--Power Press

The "B-B" line consists of machines and tools for sheet metal, tinsmiths' tools and machine dies, shears and punches of every description.

Almost every present day manufacturer is looking for the same thing—a machine capable of turning out more top-notch quality work in a day than has ever been produced before. In this way—and in this way only—can present industrial conditions be met with profit.

You realize this fact. We realize it. That's why we earnestly urge you to investigate the sturdy quality and production ability of *B.B. Power Presses.*

Canadian Machinists and Metal Workers have, in the past, been well acquainted with the B.B. stamp of never-failing service. To-day it stands forth conspicuously as the mark of thorough workmanship — through and through.

No. 17--Power Press

A complete line of canners' processing machinery; evaporating machines, special machines. and power presses for punching, forming, embossing, blanking, etc.

Let us know the machine you are interested in and complete information will be promptly supplied. If you wish advice consult us freely.

Making Ball Bearing Grinders Pay Dividends

Measured by dollars and cents, ball bearing grinders have a very definite value.

Because:

First, They will increase production. They are trouble-proof—no scraping of bearing linings nor complex oiling devices being required. **SKF** equipped grinders operate freely, quietly and without lubrication trouble. The housings are dust-proof.

Second, Motor efficiency is the most important consideration of any self-contained electrically operated machine, and to maintain the highest efficiency, it is necessary to have the most efficient bearing construction possible.

Write for special literature, also facts about **SKF** Bearings Service and the way in which it can help you with your bearings problems.

ECONOMY IN STANDARD EQUIPMENT

EVERY manufacturer recommends to his own customers standard machines or parts of regular design whenever they will actually fill the need. In this way he can offer the benefits of quantity production and carefully tested designs.

IT is the same with gages. Whenever a specially designed gage is specified, where standard equipment would serve the purpose, there is waste—waste in the original cost—waste in maintenance—and waste in the fact that the **special** gage has no permanent value for new work.

NOW is the time to systematize your gaging methods and standardize your equipment as far as possible.

JOHANSSON Standard Blocks offer a complete system of size standards f inside or outside measurements. Alrea adopted by the great majority of manufacturers in America and Europe. T surest basis of agreement as to si Permanent and dependable. Indispe sable in tool-room or inspection depa ments.

JOHANSSON Adjustable Limit Sn Gages have permanent value no mat how sizes or limits may be changed. A justing and locking arrangements so si ple and direct that gages can be quic and easily set to size.

SO much depends on relia gages, it is always econo to get the best. Write for vised catalog.

The REMOVAL of Quenching and Tempering OILS

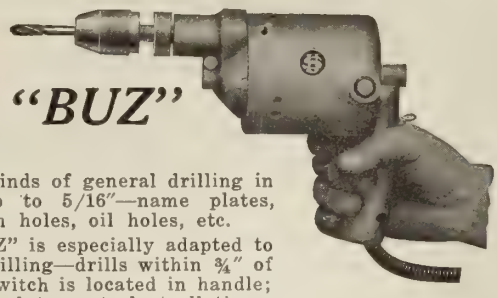
A Better Cleaning Job in ½ Time----

This Advertisement is one of a series based on actual occurrences.

AN Auto Factory uses Oakite materials for removing quenching and cutting oils from transmission gears before sand blasting, because the work shows better cleaning results and much time is saved.

Formerly soaked each batch of gears for 5 minutes in a prepared alkali solution followed by hot rinse and sand blast.

Now soak for only 2 minutes in Oakite solution, hot rinse and sand blast.



With former cleaner the parts had to be sand blasted while still somewhat coated with oil. The Oakite way leaves each gear thoroughly clean and makes sand blasting easier.

So many plants are today saving time, labor, money through the use of Oakite cleaning materials, that there is good reason to believe that your plant can also profit by their use.

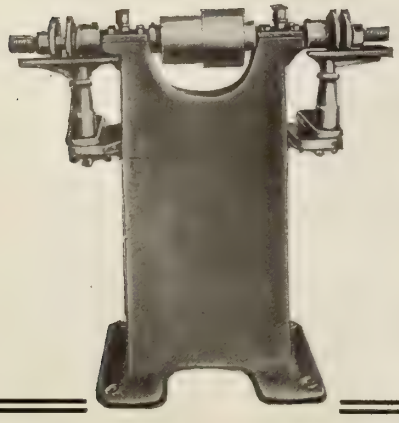
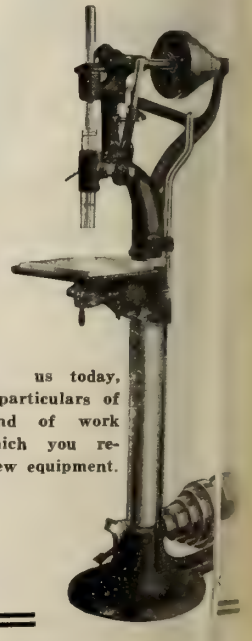
DRILLS

There are a few near-sighted buyers of machinery in this world who seem to think that it makes no difference what a machine is labelled so long as the price is low.

Surely an expensive viewpoint, because buying on a low price basis breeds dissatisfaction and too frequent expenditures.



The only really economical way is to buy from a reputation, not a price standpoint. If you buy a machine tool with a name for dependable performance—if it is stamped with the maker's certificate of reliability — the price can't help being right!



We handle only high-grade machinery and supplies that are backed by the makers, ourselves and users. We keep an immense stock always on hand and are most particular about getting deliveries out on schedule.

If you are in need of Machine Tools or Supplies of any nature our fifty years' experience should materially benefit you.

A Battery of Eight Heald Grinders Running Twenty-Four Hours a Day

Not so bad when you consider that Mr. Trindl, owner of this shop at Chicago, three years ago was running their sole machine himself. Here is the secret of his success: he had the three necessary elements—confidence—energy—and a Heald Grinder.

His confidence of the possibilities in the regrinding field has been fulfilled by the fact that it is the most active business in all mechanical lines today.

His energy and success is shown by the fact that it takes eight grinders working 24 hours a day to handle the regrinding jobs that are shipped to him from every section of the country.

And, lastly, he sticks by Heald even though many other concerns have tried to induce him to purchase their grinders. He knows the Heald is the only profitable machine for turning out high class work.

As few as three 4-cylinder blocks a day will make the purchase of a Heald grinder a profitable investment. The capital necessary is nominal; no expensive equipment is necessary; it requires no special skill to operate the grinder, because it is constructed along the simplest lines and a good mechanic can learn to become proficient in a very short time.

Take a census of the grinding companies in your vicinity. Not many are there? Perhaps none at all. Then check up the number of cars and trucks that are logical prospects for regrinding. You can then figure your possibilities as a cylinder grinding expert.

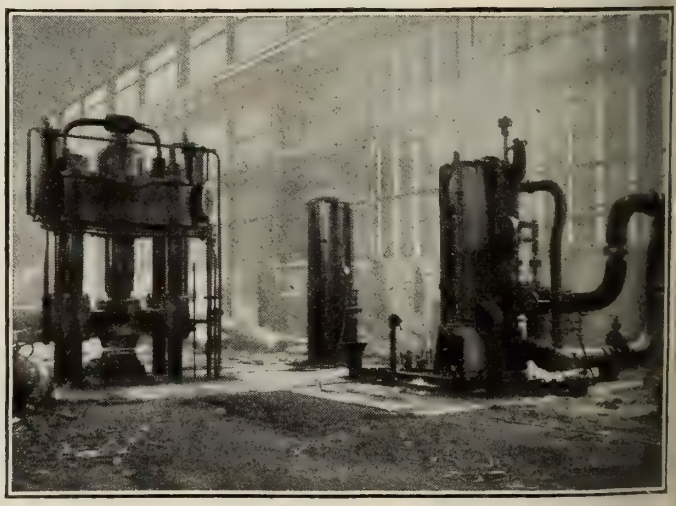
Buying a Pig in a Poke

The buying of advertising space used to be buying "a pig in a poke." The quantity and quality of circulation was shrouded in mystery and often the bag was tied against investigation.



That day has passed. The advertiser no longer depends upon "mere claims." The Audit Bureau of Circulations has untied the strings to the sack and the circulation of the better class of publications is thrown open for the most searching scrutiny.

In buying advertising space in the Canadian Machinery you are not buying "a pig in a poke." Our A. B. C. statements will stand the analysis of the most exacting investigator.

Check Your Weights on Fairbanks Scales

The ever increasing use of motor trucks has created a demand for scales to stand more severe service than the ordinary wagon scale because most trucks carry approximately 85 per cent of the load on the rear axle.

Fairbanks Scales for heavy motor truck weighing, are designed to sustain 50 per cent of the capacity rating on each of the four bearings or 100 per cent on each end.

Fairbanks Auto Truck Scales are built to maintain accuracy under the hardest service.

A Fairbanks Scale will give you satisfaction.

More Speed Better Work With

McDougall SHAPERS

16 and 20 inch Crank

Modern methods of manufacture require modern tools. McDougall 16 and 20 inch Shapers embody the best features of all machines which have been placed upon the market and can be depended upon to produce work **accurately** and **fast.**

An important feature is the column. It is massive in construction, well braced and reinforced internally. Has ample opening under ram for keyseating or other long work. Bearings for ram extend beyond vertical line of column both front and back. The ram is of exceptionally strong construction. McDougall shapers have other points of interest you should know about. **Write for full description.**

Various Examples of Vertical Boring Work

Such Machines Cannot be Considered as Production Tools Only—Intelligent Operation Will Increase Production — Feeds and Speeds Important—Crowning a Large Pulley

By J. H. MOORE

LIKE many other types of machine tools, the vertical boring mill has become exceedingly popular during e past few years. There was a time hen shop superintendents doubted the ficiency of such tools, but this linger- suspicion has long since been swept ay. The evidence in their favor has en too strong to permit of any hesita- n in accepting them for their product- value.

t is not the intention of the present icle to touch upon the design of such chines, but rather to present in photo- phic form several jobs being success- y performed in various shops ughout the country. The variety of k which can be handled by machines his nature could never be fully cover- n a short article of this kind so we have to content ourselves with a scattered examples. General manu- ring plants find them very useful many operations where turning, bor- threading, grooving, crowning etc., to be accomplished and of course,

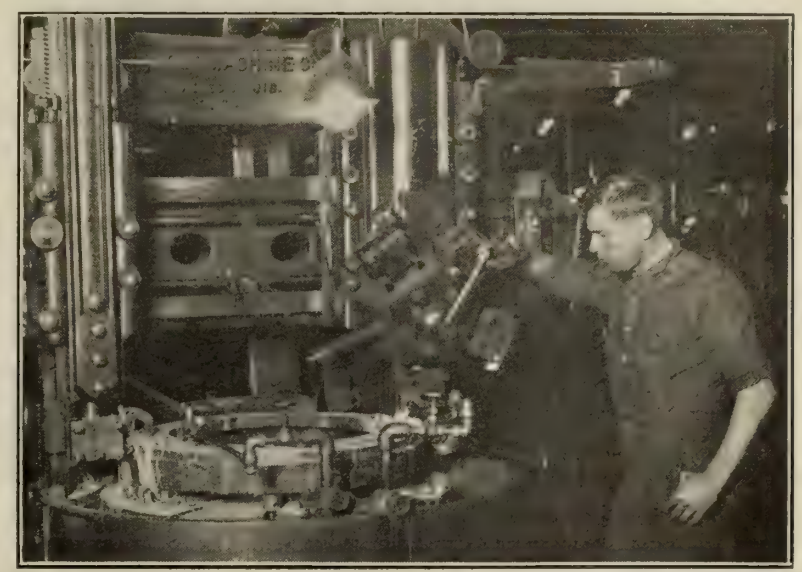

Fig. 1.—Turning a face plate gear.

as is well known, automobile factories have rows upon rows of such tools handling flywheels, cylinders, etc., etc. In the latter plants the usual practice is to set up each machine for one particular operation, turning out the work in the shortest possible time. Where the parts are being produced in sufficient quantities this is by far the best and most economical method.

tographic illustrations by courtesy of Gis- Machine Co. Zinc sketches by permission of ard Machine Tool Co.

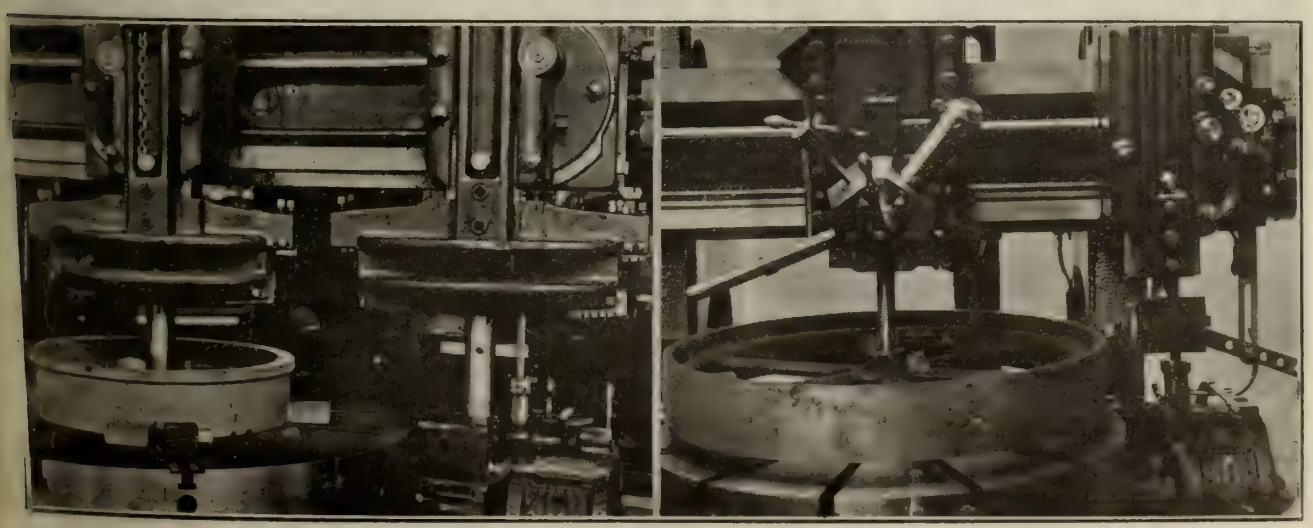

Fig. 2.—Mill equipped with special heads. Fig. 3.—Crowning a large pulley.

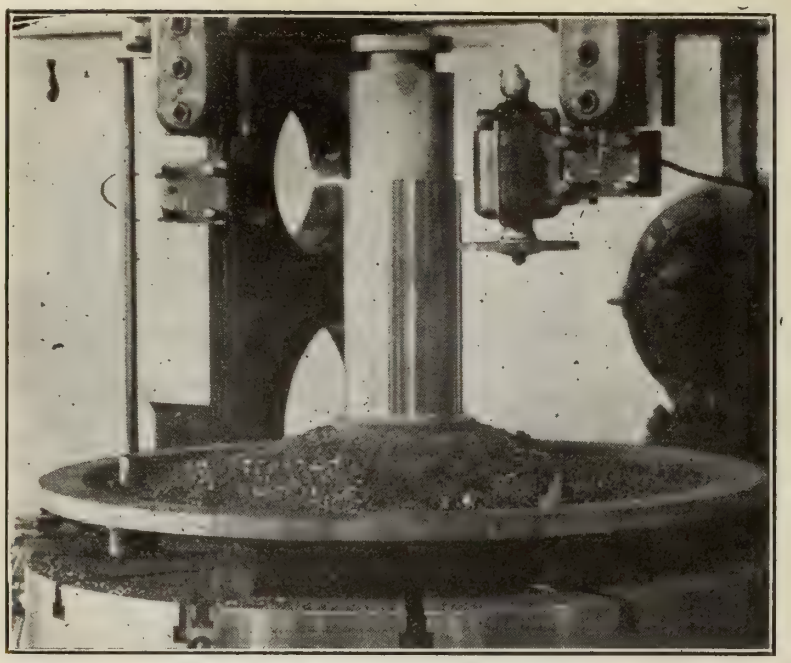

Fig. 7.—Grinding operation being performed on the vertical boring mill.

Such machines however, cannot be considered as production tools only, for in many cases they are used for general manufacturing purposes. The writer has seen as many as eight different jobs on a boring mill inside of 10 hours, each being handled quickly and efficiently.

Like any other machine tool, careful and intelligent operation is essential if maximum production is to be secured. An operator should become thoroughly conversant wtih the proper style of tool to use for the different operations; he should devise ways and means of setting up the work quickly, and should the foreman be doubtful of the need of a special fixture the operator should be able to point out convincingly, why he requires the same. Of course as a general rule the foreman is the first to see the need of the fixture and has it made to suit the mill. In spite of this assertion it is a good plan for the foreman and operator to talk things over before the jig is made, because in many cases the latter can suggest an improvement which has been overlooked.

For the general run of manufacturing work, the chuck jaws on the table are found to cover most of the requirements, so that operators have no difficulty in setting, providing they know the correct method of truing up work.

The question of feeds and speeds should also be gone into thoroughly. Manufacturers of such tools do not place a variety of speeds and feeds on their machines for the sake of saying they have a large number of gears. They are put there for a purpose, viz., to secure a large variety of conditions under which the tools can operate. An intelligent workman would never think of cutting a nickel steel forging at the same speed as yellow brass. This extreme is used to emphasize the importance of studying the proper speed to operate the machine at. Depending upon the type of finish desired, the feed will likewise be varied. There are boring mills running today which may not have come up to the plant owners expectations, but which could do so easily if they were intelligently operated.

True there may be jobs being tried on boring mills which could be better handled by some other method, but the shop manager, not the machine, is to blame in such cases. There is no need for this condition to exist for any manufacturer of boring mills is only too eager to give advice when asked. As a general rule advice of this nature is free, even to the sending of a competent operator to solve their difficulty. Having issued a few warnings as to what to avoid, we will next consider some operations accomplished on machines of this nature.

Face Plate Gear

At Fig. 1 is shown the turning of a face plate gear used at a later period for a Gisholt lathe. These castings are made of steel, and the first operation is facing the back, and turning of outside In the second operation the gear is bored in the center hole and finished on the reverse side. A special fixture for holding the part is used in the latter operation. The picture itself is well worth

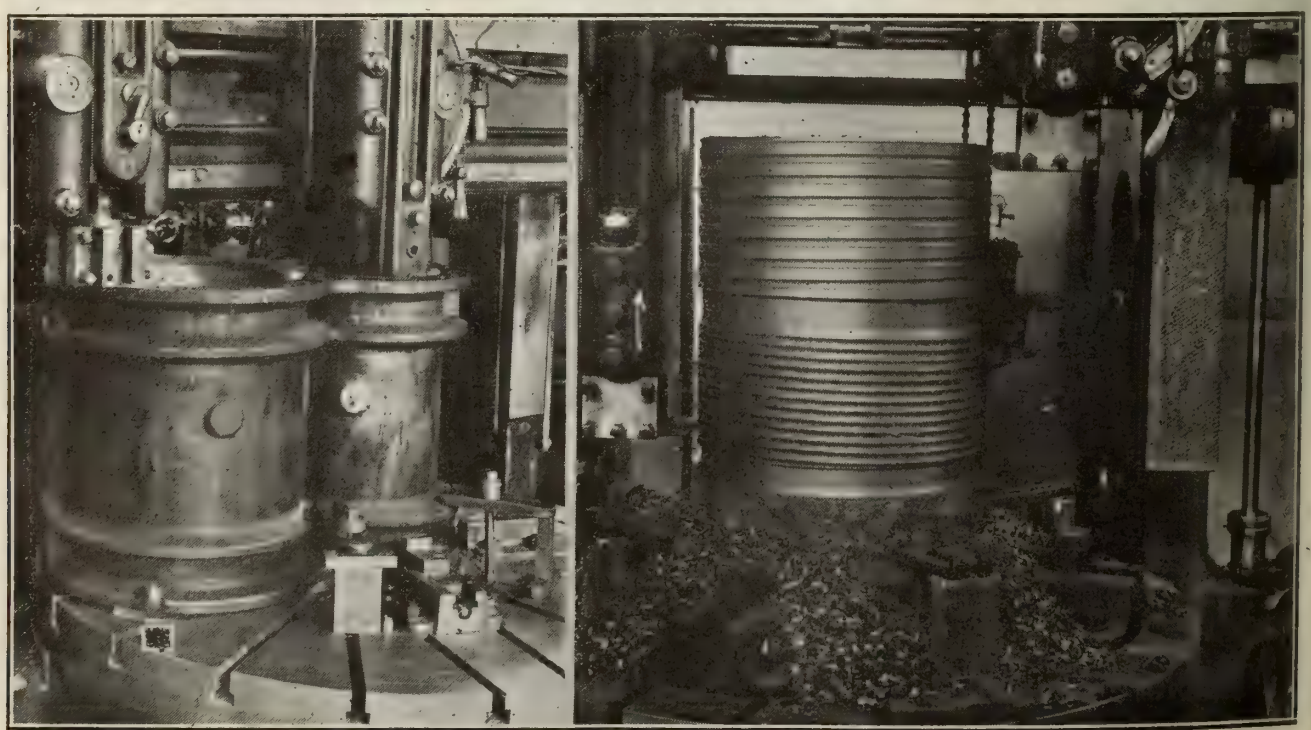

Fig. 5.—Boring out a double cylinder. Fig. 6.—Cutting heavy grooves in a drum.

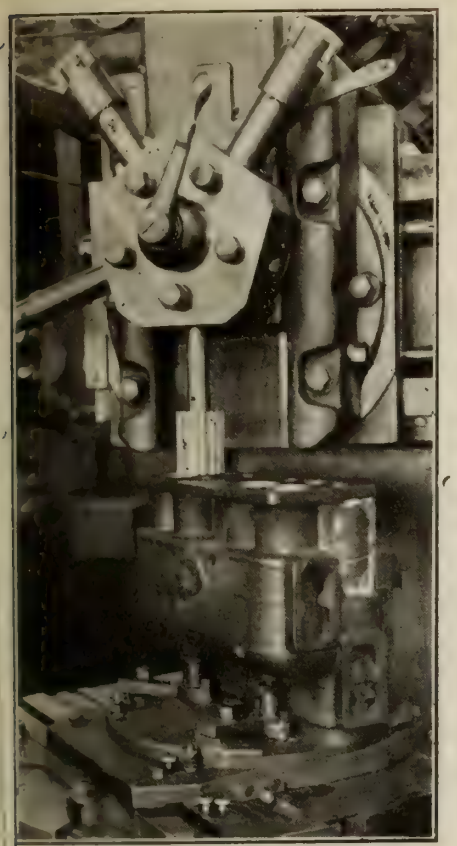

Fig. 4—Boring an automobile cylinder.

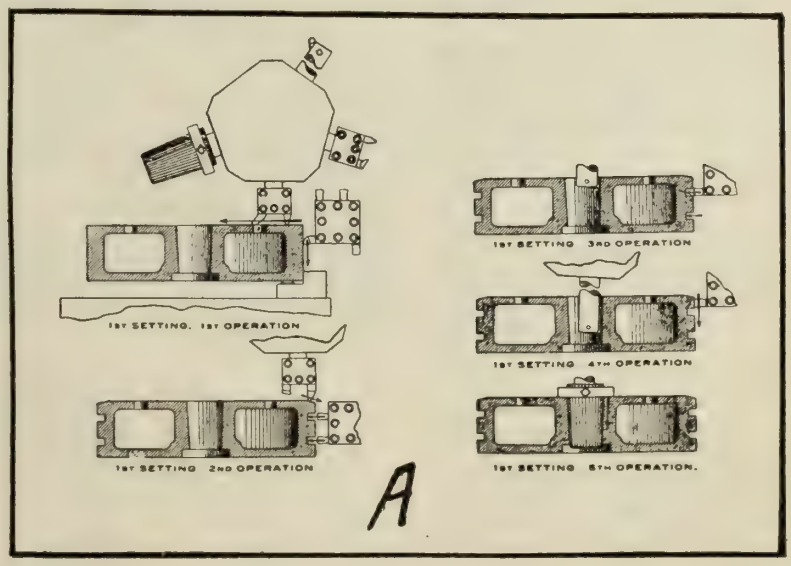
nsidering. Note the size of cut being ken, and the good stream of lubricant at is being played on each tool. If the ncern actually making these mills ink it wise to adopt this practice, why t follow out the same idea in the ps. This is a very simple operation, without further comment we will pass to Fig. 2.

Here we see a boring mill equipped th special tool heads, which have in- ased production considerably. The t shown on table is roughed out with t head to the right of machine, at t same time being rough faced on t with the upper cutters. Note the n d cutter blades which are found to b best suited for such work. The finish- r blades can be clearly seen in the e head. In addition to facing the bot- and top, a large hole is bored in the er of the casting. The finishing cut- e is hidden by the part in the photo- ph, but the roughing cutter for this can be seen in the roughing head. M boring bars used in conjunction h these heads enter a pilot bushing n e table thus guaranteeing the align- nt.

Crowning a Pulley

e next photograph Fig. 3 depicts n finishing of a large pulley even to the rowning. The first tool station fin- sh the hub and rim, and straddle faces the dius at rim, while the second sta- tion rough bores the center hole. The thir position finishes this hole, while the fourth station is used for finish rea ng. The fifth tool chamfers and face both sides of rim. After this has been completed the tool at side performs the crowning operation. The size of the pulley can be understood when we mention that the mill shown in the photograph has a table 52 in. diameter. It is hardly necessary to explain how the crowning tool is operated, for the method of securing the curve is apparent. Different curves, or crowns, can be secured by moving the connecting lever to one of the other holes.



The next example Fig. 4 shows an automobile motor being machined on a 36 in. machine. The first station rough bores the cylinder; the second position finish bores and faces the bottom; the third position reams, while the fourth tool recesses. Without removing the work from the jig which is mounted and revolves on an eccentric plate, the cylinder is revolved until the valve holes come under the boring head. When in this position these holes are rough bored, tapped, finish bored, seats faced, etc. The value of using a special fixture on work of this kind cannot be overestimated. Think of the saving in set up time, not to mention the greater accuracy secured through the two operations being completed without moving the cylinder from the fixture. The work is located in the jig by means of a C clamp which hooks over the inside of cylinder.

Large Cylinders

Fig. 5 shows a boring mill engaged on work of a general manufacturing nature. The double cylinder is placed on the table as shown, and of course the boring and facing operations are easy of accomplishment.

A rather interesting operation for a boring mill is shown at Fig. 6, this being the cutting of heavy grooves on a drum. The machine being used has a table 52 in. diameter so a good idea can be formed as to the size of the work. The upper head is cutting a double thread of 2⅝ in. pitch, the lower thread being single and 1 5/16 in. pitch. As steep as 3 in. pitch is cut on these machines. The scoring attachment can be adapted to either side of the machine, or to both as shown in the photograph. It will be noted that the left head is travelling up, while the right hand head is moving downward.

The next illustration Fig. 7 shows how grinding can be accomplished after the other operations have been completed. The piece in this case is first turned, necked and faced; after which it is

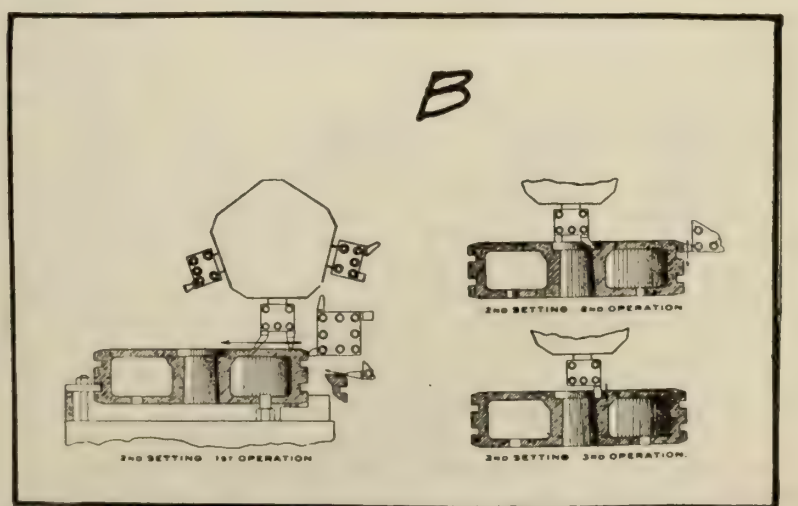


Fig. 8.—Tool layout for solid piston.

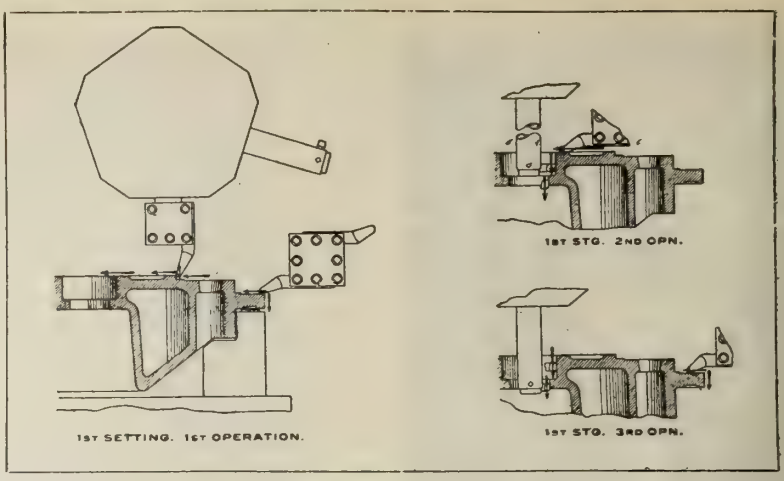
ground. A portable electric grinder is simply fastened in the regular head, the slide fed down at a suitable speed and the spindle portion ground.



The group of line drawings in Fig. 8 show a few typical jobs performed in various railroad shops where boring mills usually are in evidence. "A" and "B" shows the tool layout for a solid head piston, and as will be noted two settings are required at which five operations and three settings are performed respectively. The various sketches show clearly the tooling necessary and the arrows indicate the direction of travel of the tools.

The remaining illustration Fig. 9, shows the machining of a cast iron cylinder head which is completed in four hours. It will be noted that the head is of complicated shape and the tooling used in the set ups can be seen clearly.

Without showing any further illustrations, we will touch upon a few of the common parts completed on boring mills in railroad shops throughout the country. This type of machine handles easily such parts as pistons, piston bands, packing rings, valve rings. piston valve bushings, piston glands, and pump cylinders, cylinder heads, crossheads, brasses of all kinds, driving boxes, eccentrics and straps, throttle boxes and knuckle pin bushings, crank pin washers, hub liners and wheel bands, engine truck centers, and any cylindrical, or suitably shaped casting or piece of a locomotive.

In the general manufacturing plant boring mills are used for such a variety of purposes that no attempt will be made to enumerate them.

Speeds and feeds cannot be tied down to any hard and fast rule for much depends on the material used, the accuracy and finish desired, and the tools selected. The Bullard Machine Tool Co., have found that the following figures work out very satisfactory, and when running under ideal conditions the speeds shown below can be considerably increased. In other words the figures represent average conditions.

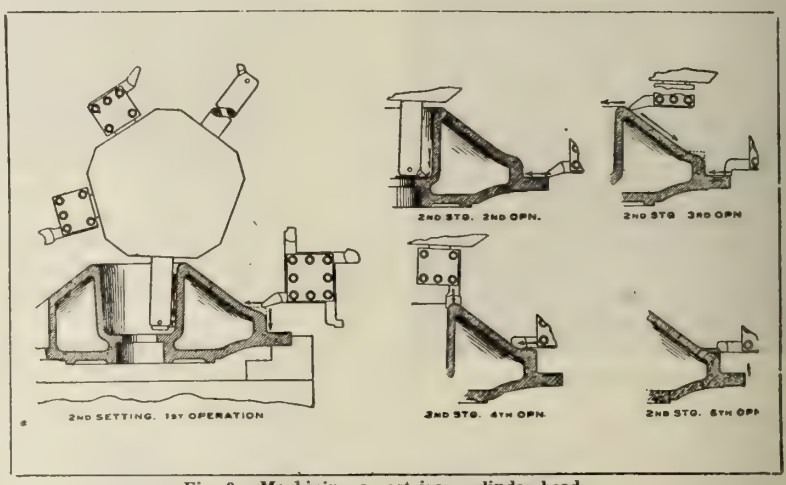


Fig. 9.—Machining a cast iron cylinder head.

Material	Turret Lathe Practice Surface Feet per Min.
Soft cast iron roughing	50 to 60
Soft cast iron finishing	60 to 80
Hard cast iron roughing	35 to 50
Hard cast iron finishing	60 to 80
Malleable cast iron	80 to 90
Steel castings	150 to 250
Brass	50 to 60
Bronze	150 to 250
Hard Bronze	80 to 100
Soft machine steel	100 to 150
Copper	150 to 200
Aluminum	250 to 400
Medium hard machine steel	60 to 80
Hard machine steel	40 to 60
Tool steel—annealed	60 to 80
Tool steel—unannealed	25 to 35
Alloy steel annealed	50 to 60
Alloy steel treated	30 to 40
Cutting threads on brass	60 to 150
Cutting threads on steel or cast iron	25 to 40

For high speed cutters For carbon cutters decrease about 50%.

CUTTING SPEED (ft. per minute.) = Dia. in inches x R. P. M. x .26

TIME TO COMPLETE CUT = Length of cut (in inches)
Feed per rev. (in thousandths) x R. P. M.

At a later date we will take up some further examples of vertical turret lathe practice.

VALVE STEEL TREATMENT

An English house organ, speaking on the heat treatment of valve steel claims that the proper heat treatment for the valves of internal combustion engines is as follows: 3½ per cent. nickel steel should be normalized at 830—850 degrees centigrade. No further treatment is necessary. 25 per cent. nickel steel should be normalized at 880—900 degrees centigrade. No further treatment is necessary. 13—18 per cent. tungsten valves should be heated to 950 degrees centigrade and cooled in still air, then reheated to 800 degrees centigrade and cooled in still air before machining. 13 per cent. chromium valves should be heated to 900 degrees centigrade and cooled in oil, then reheated to 700 degrees centigrade and cooled in still air before cooling in oil.

According to reports a new high record for production for one month was reached at the Ford Motor plant, Detroit, Mich., when 108,962 cars and trucks were produced. During April, May and June, the production of cars and trucks was 301,796, this being an increase of more than 80,000 over a year ago. The July schedule calls for 109,000 cars and trucks, and this means that a car or truck will leave the assembly line every 6½ seconds. If the schedule is maintained 4,360 cars per day will be turned out.

Micrometers as an Aid to Production Work

Their Application to Such Work Has Been The Means of Developing Special Appliances—Several Types Are Used—Details of the Most Common Styles Are Given With Explanatory Data

THE micrometer caliper, or simplified modification of the same, has become a widely used tool in machine shop practice. Their application to production work has been the means of developing special appliances for increasing efficiency. Fig. 1 illustrates several types of micrometers in general use, that shown at A, being the common one-inch size, but specially designed for heavy duty.

At B is shown a caliper designed for a wide range of work and it is particularly adapted to shops where quantity production is not a feature, but where a high degree of accuracy is required. The anvil A is so constructed as to take a number of extension posts of different lengths, the usual one-inch reading being provided on the barrel. A sheet metal micrometer is shown at C, with the graduations placed on a disc secured to the frame. The latter is so constructed as to allow measurements to be taken at a distance from the sheet edge to escape any burrs or kinks frequently resulting from punching or shearing.

For measuring the depth of holes, counterbores or shoulders, the type shown at D is used. At the rear of the depth micrometer is a set used for inside measurement of holes of varying diameters, extension rods being used in the one body.

Some application of the use of these calipers are shown in upper portion of Fig. 2. The method of finding the depth of a counterbore is shown graphically at E. The disc is placed in the recess and the distance measured; this length minus the thickness B of the disc gives the distance C. Subtracting the length C from D gives E, the depth of the counterbore.

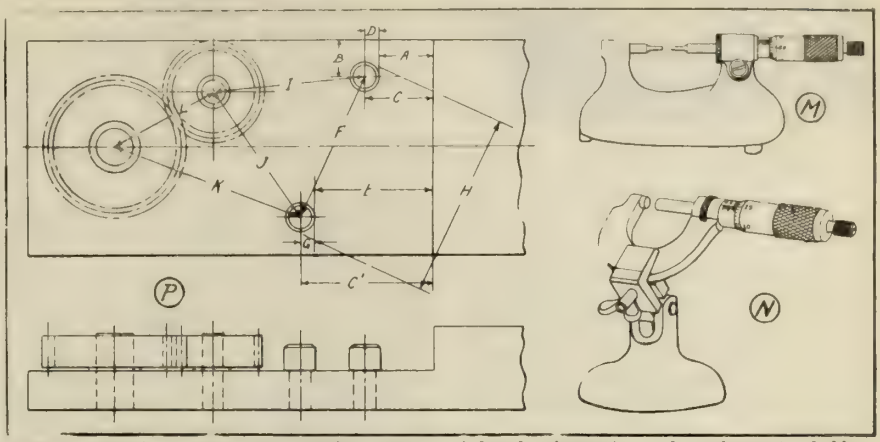

Fig. 3—Showing method of measuring centers. A bench micrometer and a micrometer holder.

The setting of boring cutters may be accomplished as shown at F. The process is similar to that just described; for the diameter I the measurement F would be (I H) 2 H. F.

At G is shown a method for finding center distances of holes or pins and the dimensions are obtained as in the other cases. In practice the tool maker would probably use buttons for determining the location of the holes and would subsequently use these buttons for locating the work in the machine prior to boring the holes. Final checking would be done as shown in the sketch.

For measuring the thickness of a hub the shallow frame micrometer shown at H is used. The tool shown at I is particularly adapted for use on soft material, the wide faces eliminating the possibility of excess compression of the material and assuring more accurate measurement.

For the laying off of work and for line measurements the design shown at J is frequently used, the scriber A being

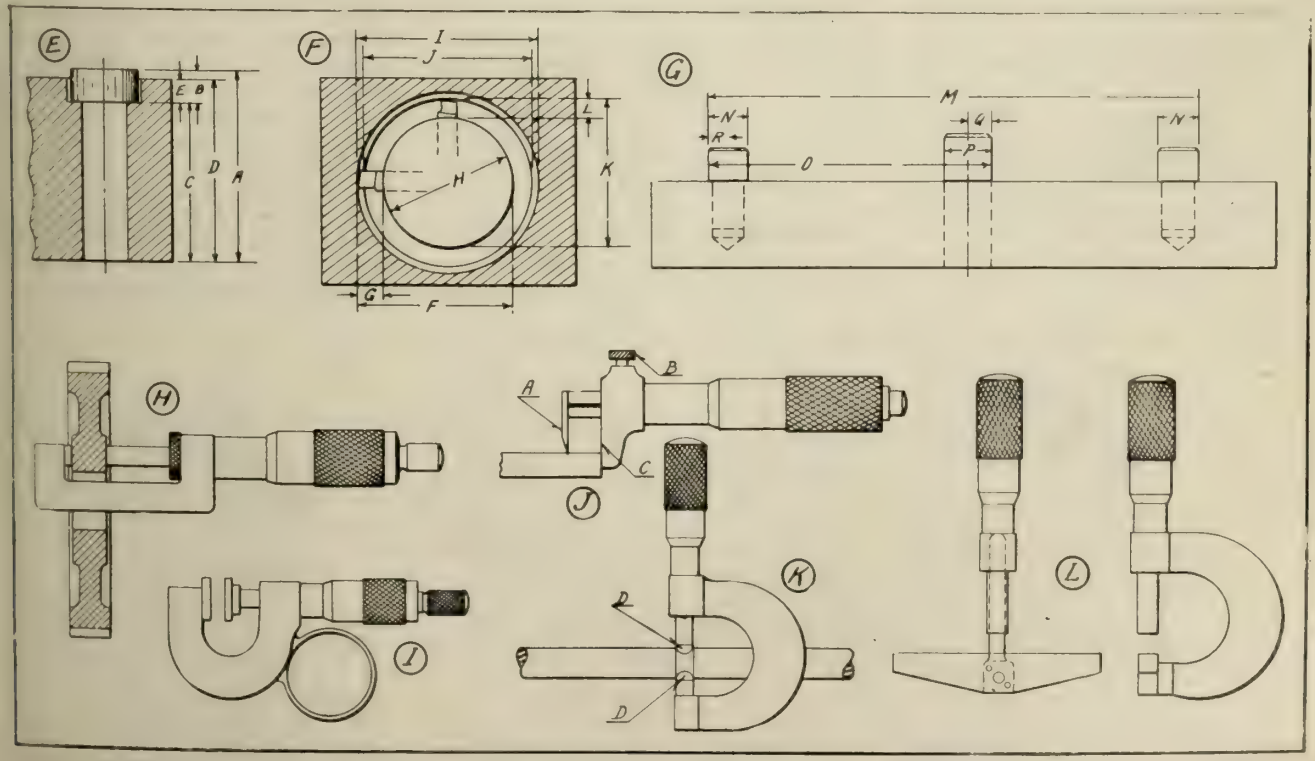

Fig. 2. The various sketches in this group are fully explained in text matter.

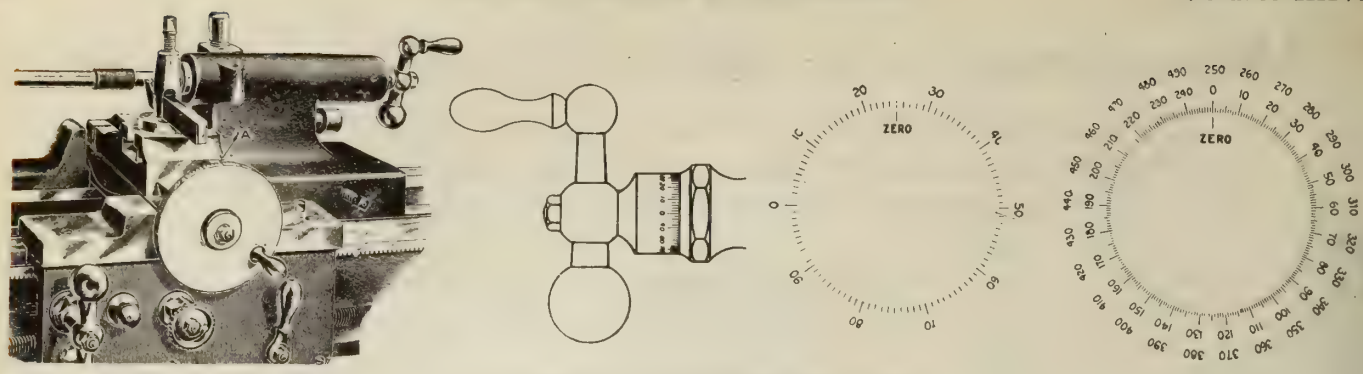

Fig. 4.—Showing the lathe dial and details of same.

secured to a special spindle, which may be clamped, if desired, by the small screw B.

For measuring grooves in shafts a micrometer with semi-spherical points D on the end of the spindle and anvil is often used; such a tool is shown at K. Another special design, shown at L, can be modified to suit varying conditions or requirements.

At M and N are special appliances for inspection purposes, where the work is brought to the measuring instrument instead of the tool to the work. M is a fixed appliance, while N shows an ordinary caliper held in a special bench stand.

In the machining of work efficiency can be increased when graduated dials are used for accurate determination of the movement of the feed screws and the advance of the cutting tools. A lathe detail and several typical dials are shown in Fig. 4.

INCREASE IN PRODUCTION

According to a statement by the United States Geological Survey, the production of fullers earth in 1920 was 128,487 short tons. This amount represents the largest output ever recorded. The output was 21 per cent. greater than in 1919; it was more than three times as great as in 1913, and nearly nineteen times as great as in 1895, the first year of production. The value in 1920 was 25 per cent. greater than that in 1919, nearly seven times as great as that in 1913, and sixty times as great as that in 1895. The average price per ton in 1920 increased only 4 per cent over that in 1919.

Fuller's earth was produced in eight States in 1920; named in the order of their rank in output they were Florida, Georgia, Texas, Alabama, Nevada, Arkansas, California, and Massachusetts. Promising deposits of fuller's earth have been discovered also in Pennsylvania and Virginia. The Southern States reported 99 per cent of the output, Florida alone reporting about 85 per cent of the total.

The imports of fuller's earth, which for many years constituted the entire source of supply, also increased in quantity and value in 1920. During the war these imports naturally decreased in quantity, and with the cessation of hostilities they just as naturally increased. The imports in 1918 were about 50 per cent. of the maximum (24,977 short tons in 1914); in 1920 they were 77 per cent of the maximum. During the war some refiners of edible oils and fats—by whom the imported fuller's earth is probably used exclusively—were unable to obtain a sufficient supply of foreign earth and were compelled to adapt domestic earth to their needs, and it may be that imports of this material will never again be so essential to the American industry.

The imports of fuller's earth in 1920 were 19,235 short tons, valued at $221,893, or $11.54 a ton. These amounts represent an increase of 39 per cent in quantity and of 17 per cent. in value. The average price at the markets of the country from which the material was imported decreased $2.13 a ton.

ANCHORING SHIFTING SANDS

An experiment will be made by the Ontario Provincial Forester to test whether the shifting sand dunes of Prince Edward county can be anchored by the planting of belts of trees in the sand areas. These sand banks, under the influence of winds from Lake Ontario have been moving inland, covering up fertile lands and rendering them useless. Tree planting has stopped shifting sands in France and other countries, and on the prairies belts of trees keep light soils from drifting. It is expected the plan will prove equally successful in this Ontario county, one of the most fertile in the whole province.

SUBSTITUTE FOR GASOLINE

According to Professor Whitford of the Yale School of Forestry alcohol could be economically manufactured from the moist vegetation of tropical forest and jungles. "The evidence is conclusive," according to him, "that the tropical sun has the power to store up more energy in the form of cellulose in a given time than has the temperate sun. If this is in a utilizable form," he says, "it remains for the ingenuity of man to overcome the difficulties of profitably applying it. With the increasing needs of the nation it is reasonable to expect that sooner or later it will be necessary to utilize more fully the plant resources of the tropics." Professor Whitford said that the annual production of alcohol from the nipa plant in the Phillipines was now nearly 3,000,000 gallons and that one distillery there had produced 93 per cent alcohol at a cost of about 20 cents a gallon, and if operated to full capacity could make it at a cost of 15 cents a gallon.

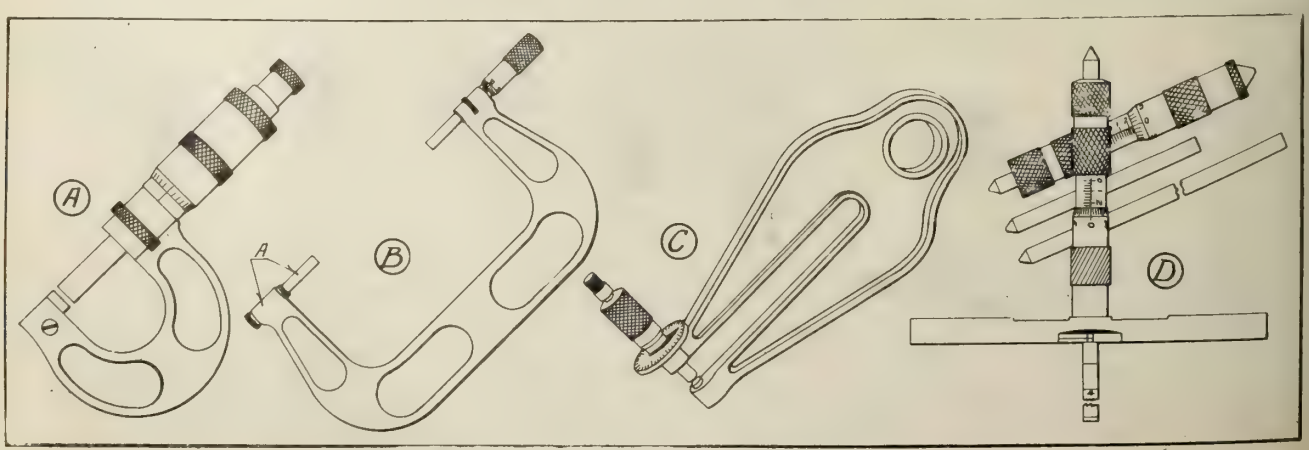

Fig. 1.—Various types of regular micrometers, including depth and inside style.

What Should Apprenticeship Mean to the Trade?

Trade Has Not Kept Pace With Educational Methods—Tendency of Modern Boy is to Avoid Work—Educational Goods Must Be Sold—A Trial Test is Advisable

*By J. E. Goss.

IN using the expression "Modernized Apprenticeships," I do so to differentiate between what, to my mind, apprenticeships would mean and what, unfortunately for the metal trades, they seem to have meant to people in general for the last ten or fifteen years. Too often do we find "old-fashioned" applied to the traditional system for training mechanics, and too often do we feel that the application is rightly made.

The causes of the transition from the old to the new estimation of apprenticeships are mainly four; the failure of the trade itself to keep pace with changes in educational methods and requirements; the false notion that learning can be accomplished intensively; the belief that vocational education in the public schools displaces training on the job, and the tendency of the boys of to-day to seek the less manual kinds of work.

As to the first cause, the trade may be largely, yet not wholly at fault. It is doubtful whether machine shop owners are giving due recognition to the fact that the high school enrollment of this country is increasing at the rate of over a hundred thousand a year, which means that each year many boys are being graduated, each boy with a supposedly better understanding as to what should constitute his trade training. To-day it is as much a matter of the boy choosing his factory as of the factory choosing its apprentice, and I believe that this is as it should be. Especially is the small shop owner at a loss to meet the changed conditions. He might not be able to afford a department, or even an individual solely responsible for the training of his few apprentices, and he may lack the facilities adequate for training apprentices as they must be trained if his apprenticeship system is to stand. Even though both finances and facilities are ample there is still the problem of their best use for the purpose. To-day public educators stand ready to co-operate with the shop, but such technique as they are able to supply will be of a minor importance to the things which the shop itself must do. More than all else is needed the interest of management. Raw stock, equipment, routing, and the rest — even vestibule training and upgrading—seem so much nearer the ultimate object that apprenticeship training is made secondary to them. There is likely to be insufficient interest in a thing seemingly so remote from profits.

The second cause should be charged as much, perhaps more, to others concerned as to shop management. The notion that there are quick and easy ways to learn has taken hold in places where it is most likely to do harm, but we must offer only constructive criticism of this and I am sure that those educators who are guilty of it will try, at least so far as our line of work is concerned, to profit by our suggestions. A short time ago I visited one of the best known technical schools in the country and was told there, by an instructor of long standing, that the institution could make a mechanic, out of raw material, in 150 shop hours. This, of course, is an extreme and ridiculous case, but it is indicative of the trend toward intensifying beyond reason the training for machine shop work. The vestibule school and the upgrading plan, so necessary to bring about certain badly needed results, have been misconstrued as an admission that industry itself had found ways to supplant apprenticeships. It seems to me that we might as well look for short cuts to experience as for short cuts to the learning of trades, for is not experience a major factor in a sound and thorough knowledge of craftmanship?

School Does Not Displace Training on the Job

As for the belief that the school displaces training on the job, there may be some shop men who have hoped that the trade school would solve their problem, but it is a question whether this has affected apprenticeships to any great extent. However, this belief on the part of educators, parents, and prospective mechanics, has had, and is having, its effect. It is not my purpose to argue against any movement tending toward a more practical curriculum in the schools. It must be said of the schools that they are making an earnest effort to turn out a more usable product, but there are still some people, at the risk of being classed as ultra-conservative, who believe that considerable effort is being scattered on various shop exercises at a time when it should be concentrated for a better understanding of the fundamentals. Even if the trade school should, in time, become a more or less satisfactory substitute for an apprenticeship system it would save no time for the apprentice. There might be some saving in time and expense for the shop, but I doubt whether the job would be as well done.

Tendency of Modern Boy

The fourth cause of the present day condition of apprenticeship—the tendency of boys to seek the less manual kinds of work—may be laid to many things. For one thing, each year more boys are completing the secondary schools and colleges, and it is quite natural that they should expect a certain prestige, allowing them to evade shop training and at once start upon the ascension of leadership. For another thing, there may appear to be—judging from some of the best national advertising copy of our day—ways in which young men may become mechanics, foremen, draftsmen, engineers, production managers, and so on, simply through part-time study. I have great regard for such study, but only as supplemental to actual experience. Then there has always been the idea that office work, physically nearer the head places, has its advantages over the shop. It seems to me that this Association is uniquely fitted to educate the people to an appreciation of the wide scope of the machinery industry and of the opportunities offered men who know shop processes through first-hand contact with them. I have faith in the stability of the boys and I believe that, with the return of normal business conditions and the "survival of the fittest" again holding good, this cause will be less marked than it has been for the past few years.

A diagnosis of our apprenticeship sickness is, of course, the first step toward the getting-well process, but it is the timely and careful administering of remedies that will count most in bringing back our apprenticeship system to a sound and healthful state. From all sides we hear that apprenticeship is dead, but those who say this either don't know what they are talking about or else they have dealt it what they thought was a death blow and left it before it began to revive. It's the doctor, not the coroner, who is needed.

The Brown & Sharpe System

Many of the shop men who visit Brown & Sharpe in the interest of apprenticeship training tell us that it would be impossible to pattern their apprenticeships after ours because of comparatively limited facilities and product, and it must be admitted that certain problems present themselves to the owners of the smaller shops. There may be some who ought not to attempt apprenticeship training at all. To my mind it is better to give it up entirely than to do it in a way that will bring little result to the shop itself and at the same time lessen the confidence of prospective mechanics and their advisers in this system of teaching a trade. But some of the most important phases of apprenticeship work are just the ones that can

*Mr. Goss, who is supervisor of apprentices for the Brown & Sharpe Co., presented this matter before the recent convention of the National Metal Trades Association.

be applied to most any shop large enough to need apprentices.

By briefly describing the Brown & Sharpe system I can, perhaps, best point out a few of the things practicable of broad application. In the first place, we recognize the fact that the propaganda of dead apprenticeships must be met with proof that apprenticeship training in some places is very much alive. Missionary work, for want of a better name, is what we might call the preliminaries to our plan. This means the publication of booklets and folders, and their distribution among people most likely to be interested in the futures of boys. All this takes time and money but eventually it shows as an asset and we have found it well worth the patience and tangible outlay. If we are to maintain a system in whi the management takes pride these things must be done—there is no choice in the matter. We would not send our own boys to a dead school, a school in which we thought educators had no more interest, in which was an untrained faculty, commissioned with something of greater importance than teaching and whose subjects might be learned in one quarter of the required time.

Educational "Goods" Must be "Sold"

Just as we meet sales competition so must we meet educational competition. We must tell people about our educational goods, more because they think that we have stopped making them. As our competitors increase in numbers and efficiency we must improve our production methods, proving by our finished product that our ways are good and that our material is the kind the management is willing to pay for. About a year ago we told the Cape Cod boys what we might do for those of them who had mechanical inclinations. It was ten months before we received an inquiry, but it will not be long before boys from the Cape will be coming to us, and what better could the grandsons of seafaring men turn to than the building of machinery? We go after good material because we want to make something out of it that we could not make out of inferior stock. If our object were to exploit a boy for four years and then put him at a job alongside another who learned the kinks in four weeks we might rely on the chance applicant from the street, but it is the backbone of our organization that we have in mind when we enter into correspondence with a farmer's boy in New Hampshire or a high school senior down on the Cape.

In line with our policy of getting good stock a dormitory for apprentices was opened nearly a year ago. It has been in existence long enough so that we know it is serving its purpose and has been successful enough, both financially and otherwise, to warrant tentative consideration of expansion. In addition to attracting boys who are used to good, wholesome homes, it is functioning as a builder of apprentice morale. Many of the associations formed at the house are sure to develop an esprit de corps which will strengthen as time goes on.

When a good product presents himself it is well to be able to show him proof of statements as to the value of apprenticeship training. Simply to tell him that nearly every executive in the organization was once an apprentice might be enough, but to walk through the engineering department and the shops and point out to him the leaders, men who once started just as he may start, means a great deal more. This is something which will take time for a shop just starting an apprenticeship system to do, but if boys are trained to hold the bigger jobs and then are consistently advanced to them it will not be long before this effective means can be used to secure the boy who shows discrimination in selecting his school. It also is well to have the prospective apprentice see with what care his records will be kept, so that he will understand that his placement as a journeyman will not depend on memory or the whim of some individual, but upon his own efforts during his apprenticeship. We like to show parents, at first hand, what we would try to do for their boy. If the home works with the shop the job is easier and better done; besides, enthusiastic fathers and mothers advertise us very effectively.

The Trial Term

Every boy comes to us on three months' trial, for, while careful selection saves time and turnover, the real test must be made on the job. It is important that this trial be given under foremen who appreciate a beginner's difficulties. Some of the best foremen on the more advanced work may be unsuited for the job of helping select the right boys, mostly because they have been used to handling apprentices well along in their courses and have lost the faculty of seeing possibilities in the face of certain shortcomings. About on quarter of the boys we take for trial are rejected during or at the end of the trial term and there have been very few boys who have disagreed with us that they were unfitted for the chosen trade. To bring about mutual satisfaction a careful report, on a printed form, is made by the foreman, shop instructor, class instructor, timekeepers' office, works superintendent and supervisor of apprentices. This is not red tape; it is what is due both the company and the boy if both are to act intelligently about entering upon further obligations.

Apprenticeship Served in Production Dept.

All the apprenticeship time is spent right in our production departments. There are some good things to be said of the segregation plan, but an experience of more than seventy years is the foundation of our judgement as to which method is the better, at least for our own purpose. To be workable the plan calls for sympathetic foremen, trained shop instructors and co-operative spirit, and without any one of these it is likely to fail. It is the feasibility of this method that is most questioned by people who visit us in the interests of apprenticeship training, perhaps because it seems like holding too closely to the old fashioned way. Time does not permit going into the reasons for our doing this, but a summation might be that we find the basic principles of the old fashioned system still sound and worthy of modernizing. This method calls for the service of shop instructors of a high order; men not only competent in their respective trades but men with tact, judgment, patience and ability to handle men as well as boys. Such men can seldom be found, even in a high grade labor market. Usually they must be selected for their workmanship and experience and for any other desirable qualities that may be apparent and then trained to do the instructing as best suits the requirements of the system.

Regular Schedule of Operations Followed

A regular schedule of operations is followed by every boy. From the lathes to the drilling machines, to the milling machines and so on throughout the course each machinist's apprentice is routed by the apprentice department. From helping to floor work, to bench work and so on thoughout his course each moulder's apprentice is likewise routed. With the boy there goes to the foreman a job analysis card, to be checked off as the steps of the work are taught, and to be returned to the apprentice department when the boy leaves, for comparison with a duplicate card checked by a shop instructor. With this is returned a printed form bearing the foreman's estimate of the boy's industry, department, workmanship and mechanical judgement, marks which are transferred to the boy's history card for a permanent record.

You may have noted that the boys are routed by the apprentice department. To my mind, the first and most important step to be taken in organizing effective apprenticeship work is to completely centralize authority and responsibility for results. There can be found today but two places in which foremen must get the permission of the apprentice department before doing anything more than teach their part of the trade. It should not be expected of a foreman primarily commissioned with the making of goods, that he will give equal attention to both production and instruction If time, or any other factor, necessitate the sacrifice of one of these responsibilities, even temporarily, instruction wil be given a second place. Occasionally w find a foreman who might carry on bot jobs fairly well, but in a shop larg enough to need apprentices it is likel that comparatively few such men wi be found. Where the work is not cer tralized it is often the case that the be ter boy gets the poorer chance to lear the trade. The foreman soon know whether or not an apprentice is going t be a real help to him in turning out

good job on time. Especially if a large rush order is in process and the boy has become familiar with the work there is reason to believe that he will become solely a producer, even though we may seek to ease our consciences by the claim that there is always something to be learned. Assuming that a foreman is a hundred per cent efficient, insofar as the apprentice while in his own department is concerned, when he thinks it time for the boy to go on the next man may be short of work to think otherwise. We all have our shop standards for production, for fire prevention, for safety, for cost keeping, then why have special departmental standards for apprenticeships? It should be understood, of course, that the foreman cannot be left out of the reckoning. He is important to the extent that he, as a group, can either make or break the system. In the shop where he and his predecessors have had full authority over the boy it is going to take a little time and considerable tactful handling to bring about a centralized plan, but it has been done in the matter of employment, the taking away of whose additional authorities must have hit harder than would those connected with apprenticeship work.

Executives Must be Educated

No matter what the organization, the management and department executives must be educated before a start is made on the boys. Some times management has a notion that a school, to teach shop mathematics and drawing, largely fulfils its obligation to the apprentice. In other words, all the thought is put into four hours out of the forty-eight or fifty that the boy spends in the plant each week. No doubt the shop school is a significant institution. Its establishment by many concerns, heretofore expecting their apprentices to continue their schooling in public night classes, has been a marked advance toward what seems to me should be our aim. As for Brown & Sharpe school work only shop mathematics and drawing are included in the regular program. Such subjects as chemistry and metallurgy are not included because we have found that the others, so essential to the shop man, take all the school time, if taught thoroughly. In addition to our regular school work, however, we have a lively library—fiction for the boy who must cultivate the reading habit and the best technical books that we can find for the others. Just now, out of 201 apprentices, there are 85 regular users of the library. A feature of the library is the training to the boys of literature pertaining to the different jobs on which they work. For example, as an apprentice is scheduled for assembling and erecting grinding machines he receives several booklets on the use and construction of these machines. As he goes to the grinding job he keeps these pamphlets and receives in addition pamphlets on the selection and safety of wheels. Questions put to him by one of the shop instructors show whether or not the pamphlets are being studied. In our lecture room the boys listen to and discuss illustrated talks on gear cutting, grinding, lubrication, purchasing, routing and the like, most of which are prepared and given by our own foremen.

A few weeks ago a committee on education, visiting our apprentice department, were surprised to learn how few of our indentured apprentices break their agreements. The only reason I can think of is, that we are giving them something that is worth while staying for. Certainly it is not because of any fear of prosecution under the apprenticeship law. If we find that a boy is the kind that honors the contract only long enough to suit his own requirements we prefer to get rid of him, the sooner the better, not only for the company, but for other boys who might be unduly influenced. Problem of keeping apprentices to their agreement works out something like this. We want a boy with a mind capable of grasping a big and important trade. Such a mind can discriminate between exploitation and a good course. If a good course is not given the mind will so discriminate and will then consider and act upon opportunities elsewhere, and another broken contract will result. We have found that boys who pass muster on the trial term are quite certain to like their work and to want to stick to it.

Placing the Man After Apprenticeship is Served

One of the most important phases of apprenticeship work, from both a practical and a physiological point of view, is the placement of a man at the finish of his apprenticeship. If we keep in mind the reason why we took the apprentice in the beginning we will take pains to see that our aim is accomplished. All that is done in connection with apprenticeship work will help to do this, but it may be well to note some of the phases of our system which directly aid in a fairly intelligent disposition of the new journeyman. Records as to industry, deportment, workmanship, mechanical judgment, attendance, class work, piece work, use of books and outside study, enable us to do more than generalize to the foreman with whom we think the graduate would be best placed. Especially at a time when new men are not being hired unless they are able to qualify under a high standard we must not expect a foreman to register a graduate unless we can show exactly what kind of a man we are asking him to take. Almost always, when an apprentice is being considered for work at a journeyman's wage, the foreman analyzes the history card. To know what twenty or more other men have thought of the boy will help to form a judgment of him. In addition to the records the course is planned so that any senior apprentice who has a definite idea as to what he wants to do may be given a three months trial at the work. This enables the foreman either to rate his new journeyman fairly or to advise us as to why the man should not be kept at his choice of jobs. Our interview system is also a factor in placement. Periodically during his course each apprentice is called to the office of an executive for an exchange of views. The interviewers make a typewritten report to the apprentice department, each executive reading the accumulative reports before calling for the boy. At first glance this may look like a cumbersome arrangement, but a little card file and a group of men with a real interest in apprentices do the job smoothly and effectively. A mutual acquaintance and the boy's knowledge of our particular work, as well as a general machine shop practice, should make careful placement a prominent feature of the whole program.

In connection with the subject of placement it might be well to express a belief which I hold regarding the number of boys accepted for training. It has always seemed to me that a shop should not take more boys than it can properly absorb upon graduation, adding, of course, a certain percentage which will go elsewhere anyway. True, boys come to us to learn a trade and not necessarily to remain in our organization, but they ought to want to stay with us and it is well to be able to keep the men who feel this way about it, and who have been tried and found valuable.

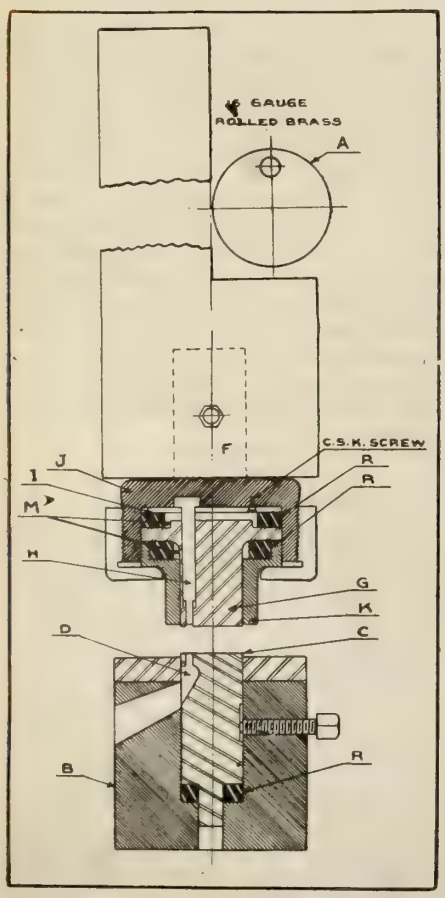
The smaller shop can do many of these things perhaps better than a larger shop can do them. For example, any manager employing only a few apprentices could call a boy to his office, even once every six months, and have the boy go out feeling that he was a real partner in a scheme to build up the business. In most cases the talk would not be one-sided; there would be something for the manager, as well as the boy, to learn.

The Brown & Sharpe system does not set itself up as an example to be universally followed. There has been found no one best way to do the training job. What some one else is doing might be copied to much better advantage. I hope, though, that I have made it clear that we find much beside instruction technique that must be put into an apprenticeship system to bring it on a plane with our other system for doing business.

SWEEPING THE SEAS

It is certain that the world at large does not realize what an enormous and difficult task it was to clear the seas of mines after the conclusion of the war. Round th British coasts 73,000 mines had been laid as a submarine barrier; and that area represented no more than a fraction of the total where mines had been sown freely. The British forces engaged in this work of clearance have swept an area about equal to the whole of England and Wales; the work was done thoroughly, but with so much scientific care for the men employed that the loss of life has been less than one per cent of the number of hands engaged.

WHAT OUR READERS THINK AND DO



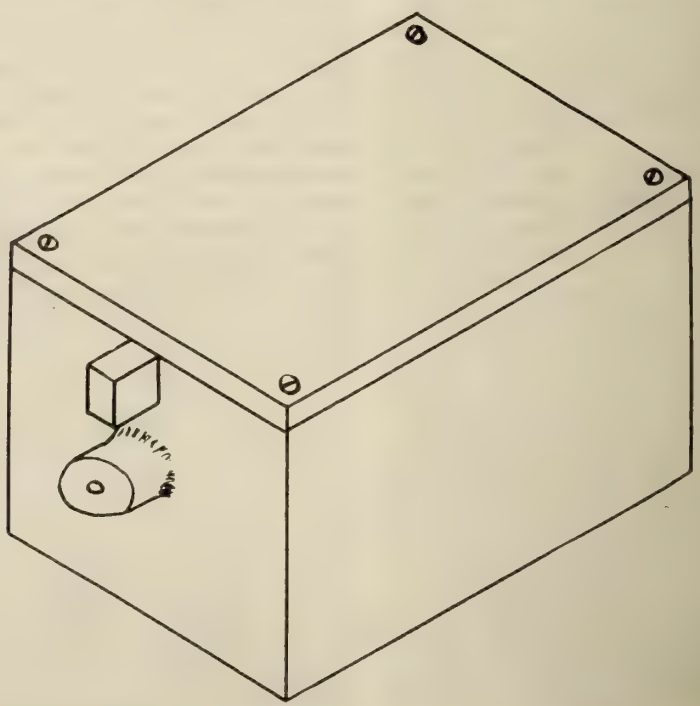
EMERGENCY JOB IN MACHINE SHOP

By T. WILLIAMS

Having a call for a number of pieces as shown in Fig. A, to be used as tool checks, I decided to make them although we were not equipped for press work. The sketch shows the part full size. The large slotter being idle, was to be used as the press, and the following description will prove interesting as the piece was to be blanked and punched in one operation.

No special castings or forgings were required, all the material being around the shop. The die holder B is a piece of cast iron machined top and bottom and dovetailed for the die, a piece of tool steel. Two side holes were drilled for clamping purposes. The block was next put in the lathe and the die and block bored to the outside diameter of the blank to the depth of shoulder shown in the section which holds the combined inner die and stripper C. The small hole was then bored for emergency use. R shows hard rubber compression rings. Die C, is a piece of tool steel turned to fit the die B, then bored and end milled as shown at D, for the small punch, and for slugs to pass out through slot end milled in front of block as shown at B. On the opposite side of C, a slot is cut for setscrew point to prevent the die from turning, but free to move vertically.

The blanking and piercing punch is shown in section Fig. F. G is the blanking punch, H the punch for the hole in the blank which is held in place in holder J, with plate I, which is secured in position with three countersunk screws, K is the stripper and also holds the stock flat while blanking. Large punch G, is stripper for small punch H, M is space for compression. The assembled punch is held in the upper punch holder shown at O, by a set screw, and in turn is secured to the slotter in the usual way with the projection underneath the ram to transmit the pressure.



Showing the tool check die.

TUMBLING BARREL FOR LATHE

By D. A. H.

The drawing shows a tumbling barrel for the lathe—a piece of equipment not usually found in the machine shop but one that is extremely useful in general manufacturing. The "barrel" is nothing more than a cast iron box, 8 ins. square by 12 ins. long, with walls ⅜ inch thick. The simplest kind of pattern answers for the foundry and, if the sides are given a little flare, it lifts out of the sand very easily in spite of its depth. Short hubs are cast on each end and on one end there is located a rectangular lug at a proper distance to engage the face plate slot and thus drive the box. Centers are countersunk in each hub and on these the box revolves. A cover of the same thickness completes the box.

Tumbling is associated in most minds with the foundry—a rough process for rough work, accompanied by lots of noise and dust. Then there is the refinement in the ball burnishing tumbling process used for very nice work in some manufacturing lines. Between these two extremes, there are the occasional jobs which every shop has that could best be done in this way if they had equipment for them—a few delicate castings that would be broken if put in the foundry barrel but which can be cleaned as well in no other way—a batch of stampings which need tumbling to remove the sharpness of the corners; a thousand round nuts from the automatic which require just a suspicion of burring; a bunch of small milled parts to be tumbled in sawdust to dry and brighten them thoroughly all over.

A rough sketch of the Tumbling barrel.

Heating The Storeroom

A PECULIAR case of improvement in heating is told by a writer in the Dodge Idea. He states that the workmen of a certain firm were complaining about the storeroom not being warm enough. Investigation showed ample radiating surface and that the heating system was working as well as could be expected of it. However, the men kept complaining about it being cold in the passage ways between the shelves, which extended up to the ceiling. In the open places it was comfortable.

It was decided that the fault lay in the solid partitions. As a remedy it was suggested that they remove the solid partition and substitute expanded sheet metal which would allow a freer circulation of air. After the change was made there were no more complaints about a cold store room.

* * * * *

Putting Waste Vapor to Work

THE method employed to increase the capacity of a heating plant for a paper mill was described recently by W. H. Howell, Jr., before the technical association of the pulp and paper industry. The capacity in this particular case was increased by the proper utilization of waste vapor and Mr. Howell stated the usual practice has been to heat fresh air from outdoors by carrying it over steam coils, blowing it into the room and taking out the moisture from the driers, either by having openings in the roof or with exhaust fans. This system has been quite highly developed and gives satisfaction provided it is properly installed.

At the mill referred to, this old system was in use, but as the production was increased about 100 per cent. it was found to be inadequate. It was then arranged to ventilate the machine room with two fans. One exhaust fan is used for pulling moist air out of the machine hood to the economizer and a supply fan distributes the warm air to various points in the room. The hot outgoing air and the fresh cold air crisscross each other in the economizer without actual contact except through corrugated plates. The object of the corrugated plates is to enable the closest possible contact for transmission of heat from hot moist air to the cold fresh air, at the same time separating the moist air from the dry air. Both fans are belt-connected to a single 20-horsepower constant-speed electric motor.

In average winter weather (34° Fahr.) the economizer is able to raise the outdoor air to 107° Fahr. for distribution in the machine room in quantity sufficient for all ventilating purposes and without the use of any steam whatsoever. This result is accomplished solely by utilizing the waste vapor going out of the machine hood and still leaving a large quantity of vapor available for other heating purposes.

It was found that 107° was too warm for the comfort of the operators, and a certain amount of moist air was consequently allowed to escape into the atmosphere without passing through the economizer, so as to bring the air temperature supplied to the room down to 98° or 100°.

Mr. Howell stated that, so far as he knows, this is the first practical use of the idea on a large scale for heating and ventilating a machine room without the use of steam from the boiler plant. By its means first-class ventilation conditions are assured in a place that formerly presented a very difficult and expensive operating condition. Of course the intention is also to use such waste heat in some cases to assist drying operation in the summer.

Selecting Proper Lubricant

"IN deciding upon the proper lubricant many factors enter in of which the average engineer has but very meagre knowledge. Oil for one purpose must have certain qualities and must undergo a certain test. This same test for an oil of different character may be absolutely useless as far as proving anything goes. It does, then, become especially desirous to arrive at some standard way of testing oil.

"The governing feature in choosing the proper lubricant," continues W. J. Bitterlich in a recent issue of Factory, "is its film-forming properties under different load conditions. In general, the lighter the oil that forms the proper film for the load pressure, the lower the friction will be.

"The simplest test of all is with the thermometer. The higher temperature of the oil in the bearing shows the greater friction loss. This, of course, necessitates experimenting with at least 1,000 or more different oils in every bearing in the plant, which is rather out of the question for many concerns. However, in this particular plant, where the oil bill amounts to $10,000 or more a year, this method shows substantial saving in power consumption and maintenance.

"The question of light and heavy oils may be settled by noting the amount of waste through stuffing boxes and felt washers. Too light an oil will leak excessively. If an oil is exceedingly heavy, however, too much power will be required to start the machinery when the oil is cold."

These two simple tests will prove good guides for the layman in the selecting of proper oils.

* * * * *

Managing An Inspection Department

"IN at least two ways the management of an inspection department differs from the management of a production department. The working force is widely scattered and the work usually varied" continues a writer in a recent technical journal, "so that coordination is difficult; the pay of inspectors is nearly always low in proportion to their responsibility, which means that it is difficult to attract and keep the right kind of workers for inspectors."

Conferences between the chief inspector and his superintendents and foremen, binders for each member of the inspection department in which to keep the proper bulletins and instructions, and the development of the spirit among the members of the department to make their work most effective, are, without any question, three important ways of getting better coordination from the inspection department.

The nature of the work of inspectors makes it difficult to pay on any except day rates, and it frequently occurs that machinists on piece rates earn more than the men who inspect their work, and this naturally causes discontent. A definite rate of promotion with grade rates of pay based upon length of service, in combination with efficient work, is one of the best ways of avoiding continual requests for wage increases and general discontent among inspectors.

Foremen inspectors often request insistently that more and better inspectors be supplied, under the impression that the larger the number of men working the larger and better will be the output. This argument can be successfully met by showing that while this is true up to a certain point, beyond that point the more men present the more congested conditions will be and the less total work that can be accomplished. Rather than more men, it is a matter of increasing the efficiency of the allowable force.

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

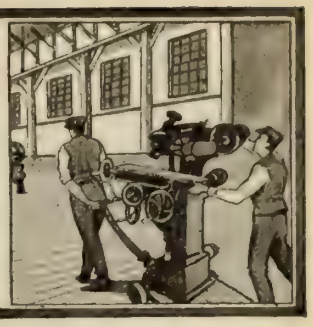
We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Three contestants had correct lists for the August 25th contest, these being John M. Campbell, Thessalon, Ont.; Ernest V. Bell Fredericton, N.S.; and George Land, Peterboro, Ont. They were drawn in order mentioned so that Mr. Campbell gets the scale this week. Better luck next time Mr. Bell and Mr. Land, but the rule is the first drawn gets the prize. The winning lists are laid face down, and a total stranger, who knows nothing about the names on the papers, draws them out in rotation. We thus eliminate distances and make it fair to all.

CONTEST FOR SEPTEMBER 15TH ISSUE.

Contestants are required to write us, stating to which advertisements we refer in this number.

1—Something to keep a watch on.
2—A machine that will work faster and better per minute.
3—Can be used in both war and peace times.
4—The difference between two arts.
5—Something adopted in America and Europe.
6—A field where things are cheerfully furnished.
7—Something where the body, glands and even a bonnet are made of brass.
8—Has an eccentric relief but does not chatter.
9—An advantage for unskilled help.
10—A product with an open hearth.
11—His bread and butter depend upon it.
12—A chamber for refining.



These are Correct Answers for List from August 25th Issue.

1—John Bertram & Sons.
2—Nicholson File Co.
3—Gisholt Machine Co.
4—Dalton Mfg. Co.
5—American Pulley Co.
6—J. T. Hepburn, Ltd.
7—Carlyle Johnson Machine Co.
8—Cleveland Pneumatic Tool Co. of Canada.
9—H. H. Robertson Co.
10—L. S. Starret Co.
11—Roelofson Machine & Tool Co.
12—The Shore Instrument Co.

Closing Date for This Contest is October 6th

DEVELOPMENTS IN SHOP EQUIPMENT

HEAVY DUTY GRINDER

The Van Dorn Electric Tool Co. Cleveland, Ohio, have perfected and put on the market an improved heavy duty ball bearing electric grinder driven by a 4 horse power motor. Two 14 inch diameter by 2½ inch face grinding wheels, slip direct on the ends of the motor shaft, so that the full power of the motor is used for work. The wheels are quickly changed by removing four bolts and the end flanges from the heavy non-movable wheel housings, these in turn furnishing ample protection from bursting wheels. Provision is made on the wheel guards for connecting to the exhaust ducts when desired; besides a lug with a hole permits the attaching of an eye shield on each guard.

The tool rest is conveniently located with both horizontal and vertical adjustments; and the aluminum water pot, which is easily lifted out of place, sets in the proper position to be reached by a short movement of the arm. A Van Dorn built polyphase induction motor, designed especially for this grinder, embodying all the features necessary for heavy duty grinding operations, furnishes ample power for both wheels. It is insulated, tested and rated by A. I. E. E. standards. The rating is 4 Horse Power for normal continuous operation and 7 Horse Power for a momentary overload capacity. The standard motors operate on 3 phase, 60 cycle alternating current, with either 220 or 440 volts. Special windings such as 2 phase, 60 cycles, or 3 phase, 50 cycles, with either of the given voltages, are only made on special order. The speed of the 60 cycle motor is 1,200 R. P. M. and for the 50 cycles it is increased to 1,500 R. P. M.

Another feature is the completely enclosed, dust proof, motor housing, smaller in diameter than the grinding wheels, so that ample movement of the operators hands are possible without touching the machine and also preventing interference when grinding long pieces. A fan within the motor furnishes positive ventilation under all normal conditions; but where excessive dust is encountered, provision is made for piping a supply of fresh air to the intake end of the housing. To insure accurate operation, a minimum amount of friction, and decreased power consumption; the motor shaft is set in extra large ball bearings that are rigidly supported directly beneath by the housings which are continued down to the pedestal top where they are bolted. Lubrication is accomplished by inserting the grease-gun nozzle in the grease ports located directly above the bearings.

The pedestal is built heavy and rigid to prevent vibration; at the same time it serves as a safe and easily accessible enclosure for the switch, fuses, and connections. The cable conduit enters through a hole in the back, so that no wires or electrical appliances are exposed at any point on the machine. This grinder is started or stopped by a pedal switch located at the base of the pedestal. The center of the spindle is 39 inches from the floor. Grinding wheels are set 25 inches apart thereby permitting two operators to work without interference. A floor space of 22¼ inches by 24 inches is covered by the base. The net weight of the grinder is 696 pounds.

DRAW-IN CHUCK ADAPTER

The Phoenix Tool Company of Bridgeport, Conn., are now manufacturing a self-contained adapter that can be applied to any engine lathe or milling machine for the use of draw-in collet chucks without the use of a draw-in bar or the need of a hollow spindle. The operation is by means of a knurled nut on a piece at the forward end of the adapter. These adapters may be furnished to take any standard spring collet. The shanks are made to fit any taper or adapters may be secured unturned so that purchaser can adapt it to any machine desired.

ROTARY WIRE BRUSH

The Independent Pneumatic Tool Company, of Chicago, Ill., has developed a rotary wire brush that can be used on either their electric or pneumatic portable tools. The brush for the former is smaller than that used on the electric machine, owing to the greater speed of the latter. The brush is so constructed that the wire may be replaced when worn out without destroying the holder. The device is particularly adapted to the removal of paint, rust, scale, etc., from the bodies of steel cars, automobiles, castings and sheet metal.

A Step In The Right Direction

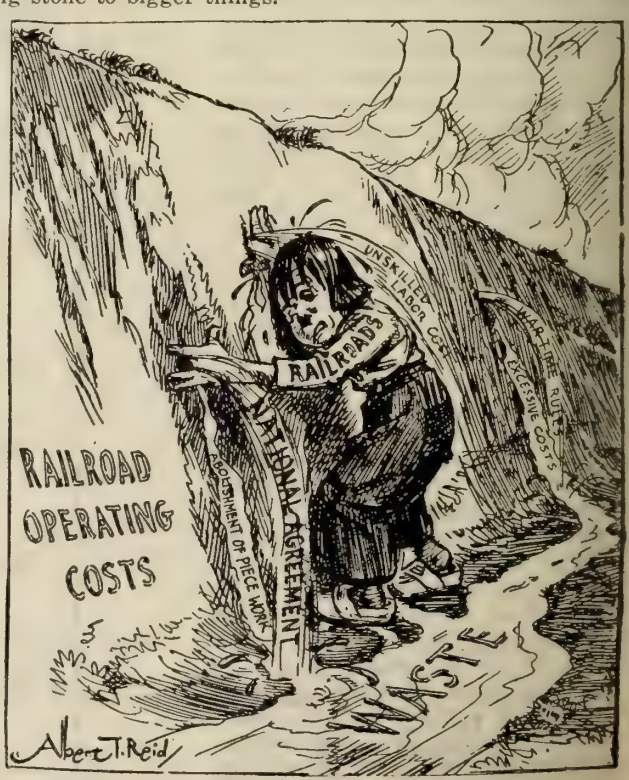
THE most important step which has been made by the Toronto Fair directors within the last ten years occurred last week. This was the calling together of the various representatives of the machine and tool engineering trades, to discuss the advisability of erecting a new machinery hall. The result of this meeting, which will be the first of many, is reported elsewhere in the present issue.

It has been recognized for some years past that the machinery building at present in use is obsolete. Apart from the fact that it is out of the beaten path, the building itself is far from suited for the exhibition of machinery, especially of the heavier variety. There are no lifting facilities whatever, so that anyone showing heavy machinery has to lug it by brute force to the desired position, providing it does not go through the floor in the meantime. It has been in this condition for some time past, but in view of the earnest effort which the directors of the fair are making to erect a suitable building let us look forward rather than backward.

The machinery show this year is far superior to any other previous year. Mr. Murray, who has had charge of this building for many years says so himself, and he ought to know, for he is a keen judge of merit. If this holds true with an old building, what can we not accomplish with a new modern structure. Canadian machine tool builders, and makers of other engineering and electrical lines have nothing to be ashamed of in the design and workmanship of their products. Rather, there is real cause for pride, and it is up to every manufacturer to get behind this movement. Let us show the directors we mean business, so that they will erect a hall large enough to house not only machine tools but all lines of the engineering trade. Electrical, Steam, Mining, Moulding, Printing, Pulp and Paper, in fact all lines of machinery should be represented. We cannot make the scope too wide. Let us do away with the term "Machinery Hall," calling the new edifice "General Engineering Building" or something of that nature.

Each manufacturer should decide what space he desires, submit this to the chairman of the investigation committee appointed, when they in turn can have a tentative plan drawn up, submitting this both to the directors and manufacurers. Even in the event of such a plan being prepared, provision should be made for extension, so that those concerns who may be timid about coming in at present, can do so at a later date. Not that there is anything to cause the slightest hesitation, for Canada has a wonderful future, but there is always an element existent that wants the other fellow to take a chance. There is no chance in a venture of this kind. The manufacturer who stays out of the new hall is simply losing a wonderful opportunity to show people what he is accomplishing.

Next in importance to the building itself comes the question of location. This point should be watched carefully for to get the greatest benefit of such a structure, it should be convenient to the public, yet handy to the railroad tracks. It is quite posible that suitable tracks can be laid from the main line. which can run directly through the new building. If this is done, so much the better.



The gentlemen who asembled last week to discuss the erecting of this building are to be congratulated upon their choice of a committee. It is a well balanced one, and the moral support of both the Electrical and Mechanical Engineering societies will doubtless be felt before final arangements are completed.

* * * * *

An Opportunity for Young Men

"TELL the young men of your journal that there is a wonderful opportunity at their very hand." Thus spoke a well known business man to Canadian Machinery a few days ago. On investigation we found he was referring to the possibilities of stenography for young men. Personally, he said, he was sick and tired of girls whose chief aim and object was dress, not business. "Show me the young man who really wishes to be something; let him start as a good stenographer, working up gradually," he continued, "and I'll make a success of him."

Come to think of it, and what do we find? That many men occupying president's chairs at the present time were formerly humble pounders of the typewriter keys. This thought would be well to bear in mind for provided a young man is serious in his intentions, the art of stenography is actually a stepping stone to bigger things.

Trying to save the dyke, as Reid of New York World, sees it.

MARKET DEVELOPMENTS

Steel Production Shows Considerable Increase

In Six Weeks the Production of Steel Has Increased Over One-Half—Price Increases Are Announced in Wire Nails—Machine Tools Are Moving Slowly—Scrap Market is Very Dull

THE market shows a few increases this week, these coming into effect September 12th. Wire, and wire nails are the products which have been boosted in price. The advance came as a surprise to those who had not realized that steel prices in general were very near rock bottom.

Steel production shows considerable improvement, having increased by a little more than half, during the past six weeks. The stiffening in pig iron prices is regarded as representing a movement up towards actual cost, as some furnaces have been selling stocks at below cost, in anticipation of lower freight rates coming into effect. The freight reductions have not come, while on the other hand, the stocks of many furnaces are gone.

The railways seem to be hanging off as long as possible. They are purchasing only what they actually require.

The small tool market marks time. We cannot report an increase, nor can we say the situation is poor, for it's not. The various dealers say they cannot complain considering the circumstances.

Machine tools are rather easy this week. Last months big business was really the closing up of various deals which had been hanging in the balance for some time. Dealers however are not discouraged. They say that the confidence existent, speaks well for the future. The scrap market refuses to wake up. Nobody seems to want to buy, and the dealers themselves do not care to stock up further even at prevailing prices.

STEEL PRODUCTON SHOWS INCREASE PRICES ARE BOOSTED IN SOME LINES

Special to CANADIAN MACHINERY.

PITTSBURGH, September 15.—Computations based on the monthly report of the American Iron and Steel Institute show that production of steel ingots in August by all the producers was at the rate of about 15,800,0000 gross tons per annum, or 30 per cent. of capacity, against a rate of about 11,100,000 tons in July, or 21 per cent. of capacity. As production at the middle of July was slightly below the average rate for the month, and production was increasing during August, being at the end of the month above the 30 per cent. shown as the average of the month, the rate of steel production increased by more than one-half in a month and a half. The official statistics furnish ample confirmation of our recent reports of continued improvement in demand upon the steel mills.

Of course the rate of steel production cannot be expected to increase by one-half every six weeks, but it is quite likely to increase some more in the next few weeks, and a rate of about 40 per cent. will probably be attained before the end of the year. More than this can hardly be expected for this year, but in early spring there can easily be a further increase, and in all probability there will be. There is not the slightest ground for thinking the rate of production will ever again go below 20 per cent. as it did in the fore part of July.

The Steel Corporation's unfilled obligations at the end of August are reported at 4,531,926 tons, showing a decrease during August of 268,368 tons, this comparing with decreases of 287,544 tons in July and 364,619 tons in June. The August decrease was equal to 21 per cent. of the month's capacity, there being 27 working days while capacity is taken at about 52,500 tons per working day. Shipments in August may be estimated at 30 per cent. of capacity, and with 21 per cent. decrease in unfilled obligations the new bookings in the month seem to have been 9 per cent. of capacity. For six months past the bookings have been very light, the business filled by the corporation being chiefly by shipments against old contracts. This has caused misunderstanding in some quarters, where a decrease in the "unfilled obligations" is considered a bad thing.

From that viewpoint July would have to be considered a "better" month than March, because in July the unfilled tonnage decreased only 287,544 tons, while in March it decreased 649,102 tons, but the fact is that the shipments in March were correspondingly greater than the shipments in July, and thus March was a much better month. It is the shipments that bring in the money, not the contracts that customers fail to specify against. Some people in Wall Street, however, seem to think otherwise. In these same Wall Street circles there has been complaint lately that "there is no forward buying" as if the mills would like to fill up for a full operation Christmas week no matter how nearly idle they are at present.

A Steel Price Advance

Effective Monday, September 12, the American Steel & Wire Company has advanced its price $2 a net ton on plain wire and $3 on nails and barb wire. The advance has come as a surprise to those who had not realized that steel prices in general were necessarily very near bottom and in some lines were ripe for an advance. The new prices are: Plain wire, 2.60c; galvanized wire, 3.10c; painted barb wire, 3.05c; galvanized barb wire, 3.55c; wire nails, $2.90; cement coated nails, $2.50. The independents are making corresponding advances but as the policy in the wire trade has always been to book customers ahead a little distance before requiring them to pay advances it may be a few days before all the independents have put the advances actually into effect. The reductions to 2.50c on plain wire and $2.75 on nails occurred early in July, and from that time to the advance this week there was practically no shading, the prices being very low indeed by relation to the cost of production.

Outside of wire products, the stiffest line in finished steel products is sheets, which for three weeks past have been at 2.25c for blue annealed, 2.75c for black and 3.75c for galvanized, with no

shading except slight concessions in the southwest, where there is competition between production districts. These sheet prices when made were regarded as altogether too low in relation to cost of production and there is a possibility that there will be a slight advance in the near future.

Bars, shapes and plates, on the other hand, have continued to exhibit a slight sagging tendency in the open market. This is not a decline in the extreme prices, possible on the most desirable business, but is rather a relaxation in the restrictions that make an order particularly desirable. Large orders are no lower than early in August, but small orders are lower, and are nearer the price of large orders. Bars, shapes, and plates may now all be quoted at $1.70. Some business has been going at a little higher, but not a great deal of business, while concessions below this level are small, and are given only on very desirable orders. Late in July the open market, on single carloads, became established at $1.75 for bars and $1.85 for shapes and plates.

Current demand is heaviest from jobbers, particularly in the south and southwest, and is moderate from manufacturing consumers, the smaller manufacturers apparently doing better than the larger, presumably because the latter had the larger stocks. Demand for construction purposes, and from railroads, is very light. By products, sheets show the best demand, and the scale runs down through tubular goods, wire products, tin plate, bars, plates, shapes and rails, the last named showing the lightest demand.

Pig Iron and Coke

The stiffening tendency in pig iron prices, more or less in evidence since the middle of August, is still seen, but price advances are regarded as representing simply a movement up towards cost, furnaces having been willing to sell stocks at below present cost, in anticipation of reduced costs in future by reason of freight rate reductions. The freight reductions, however, do not come while the stocks at many furnaces are gone. Foundry iron at valley furnaces is up 50 cents to $21, furnace, this being the third 50-cent advance.

There have been curious and interesting developments in the Connellsville coke trade. By a series of wage reductions the independents, which means all producers expect the H. C. Frick Coke Company (Steel Corporation) got down to the scale dated July 1. The Frick Company reduced twice, but the second reduction, August 1, left its wages between 10 and 15 per cent. above the independent scale. Then, late in August, W. J. Rainey, Inc., one of the largest independent operators, attempted another reduction, producing strikes and threatening trouble elsewhere. In the past week most of the independents have advanced wages to the Frick level. The coke market has stiffened at least 25 cents. The market for spot is not under $3 25 for furnace and $4.25 for foundry and it is a question whether much can be bought even at those advanced figures.

POINTS IN WEEK'S MARKETING NOTES

Pig iron is up a dollar in Montreal. A fair business only in this line is reported. Scrap metal still remains the black sheep. There is nothing being done and little hope of improvement in the near future.

The railways seem to be hanging off as long as possible, purchasing only what they actually require. Used tools are selling in Montreal, one dealer claiming that he has about three enquiries for re-manufactured tools, against one for new tools.

In Montreal the quotation on bars, rails, and structural shapes are down to about production costs. Structural steel is moving in small quantities, while sheets and tank plates show a little additional activity.

Steel production shows a good increase in the Pittsburgh district. In a month and a half the production has increased a little better than one half.

Plain wire has gone up $2.00 a ton; nails and barbed wire have increased $3.00, and the new prices which came into effect Sept. 12th are as follows:—Plain wire 2.60c.; galvanized wire, 3.10c; painted barb wire, 3.05c.; galvanized barb wire, 3.55c.; wire nails, $2.90; and cement coated nails, $2.50.

Pig iron prices are very much the same as last week, and the recent stiffening in prices is regarded simply as a movement up towards cost, as many had been selling stocks at below cost, in anticipation of reduced freight rates.

The Toronto machine tool market is rather quiet this week, although some good prospects are being brought to the point where business is expected. It looks as if the various firms do not wish to spend their money just at the moment, for in many cases the equipment is badly needed.

The small tool market moves along in steady fashion. Business keeps coming in, but only in small lots, for manufacturers are still hanging on to the buy as you need it policy. The scrap metal market refuses to come to life. Things are very dull, and a quick unveil is not looked for.

TORONTO MARKET REMAINS STEADY

TORONTO, September 15.—While there is nothing startling to report this week, the growing feeling of confidence is, in itself, worth while. Speaking to one machine dealer Canadian Machinery enquired if the present lull in buying could be attributed to firms waiting for still lower prices. "Lower Prices" exclaimed the dealer "what do you mean lower prices."

He then went on to say that in his opinion the lowest possible price had been reached, so far as his particular line was concerned. He pointed out that reductions had already been made which fully covered the drop in the other commodities. "To my mind" he continued "there is not another thing sold on the market which gives back such quick returns as machine tools. When you purchase a machine, you do so in order to increase production. The added work you turn out soon pays for the equipment, and any maintenance you may have in later years is very small in comparison with the profits you make. That is," he concluded "if you purchase high quality tools, and take care of them."

He then quoted two examples to prove his former remarks regarding maintenance. He said that no later than a few days ago he ran across two machines which had been in use over ten years, turning out accurate and heavy work, yet the maintenance on both tools had only been around $25.00.

As far as selling machine tools is concerned, the various dealers interviewed state that while business is being secured it is not quite as large as last month. Several good prospects are being lined up however, and when they decide to spend their money, the size of the orders should be worth while.

The small tool market remains very much the same as last week. We are getting about the same quantity of orders, remarked one dealer, and we expect to do likewise next week. We cannot complain under the circumstances, and while no sudden improvement is looked for, we expect the business to be steady. There is no change in prices, and like last week, our customers are only buying what they actually require.

Scrap Market

Everybody seems to be up in the air regarding the scrap market. How some dealers continue to remain in the business is a mystery to many, for there is absolutely nothing doing. Nobody seems to be anxious to buy, and of course dealers refuse to stock up further. In many cases these stocks are very heavy and any further buying movement would only make a bad situation, worse. Evidently the scrap dealers have a side line which nets them some profit, while they wait until the regular market shows signs of life.

The Steel Market

Structural material is still selling fairly well. The other lines are moving

at a fair rate of speed, in fact the market is passing through a regular seasonable improvement. There has been no change in prices, nor is there likely to be any for some time. As one dealer puts it, prices are pretty near the bottom anyhow, so any changes that will occur will likely be in an upward direction. Such changes will be gradual however, so that the buyer can enter this market with a good feeling of safety.

SHEFFIELD MEN VISIT MONTREAL SECOND HAND TOOLS ARE OFFERED

Special to CANADIAN MACHINERY.

MONTREAL, Sept. 9, 1921—Little change in business circle has been noted in the past week. The slightly better tone in some lines that has been noticed for the past two weeks has been sustained, but still business is far from being normal in most lines of the detail working industries. This week Montreal has entertained some very prominent steel magnates from Sheffield. These men have been in Washington voicing their objections to the new Fordney tariff. They do not make any very startling prophesies of an immediate improvement in the steel industry of Britain. They state that the natural resources of Britain are such that she ought to be able to produce steel cheaper than Germany or the United States owing primarily to the fact that coal and ore are found within a few miles of each other.

In the case of Germany and the United States, a long rail haul is usually inevitable in bring coal to the ore, and then a further rail haul to the seaboard for export. In Britain the coal and iron mines and the seaport are all within a circle of thirty miles. Of course the old problem of labor comes up and if labor is unreasonable why the natural advantages will be offset. At present little or no British steel is being imported into Canada. It is understood that at present the British mills are trying to re-establish their old conditions.

Structural steel is moving a little in small quantities while sheets and tank plates are showing a little additional activity. Pig iron has again stiffened in price but the consumption is very small. Little or nothing is being done in the non-ferrous metals, while the scrap metal market has shown no signs of recovering.

Steel Market

Very little improvement over last week can be reported. The mills are taking a number of small orders and are trying to keep their plants in operation as it would be a very costly matter to allow their various furnaces to stop active operations, then later to blow them in again. Thus the quotations on bars, rails and structural shapes are down to about production costs. A few odd orders for medium heavy plates have been placed in the last week or ten days for tank work. There is also the usual increase in sales of sheets for stove pipe work and for range boilers. This is only a seasonable improvement and in a few weeks the demand will have fallen off again. Bars are very quiet, in fact, no sales of any moment have been reported. In Montreal vicinity there is more or less building in progress and a small demand for structural steel is noted, but the season for building is nearing a close and the business will drop off in the near future.

Machine Tools

The manufacturers of machine tools are still asking war time prices for their product which keeps prospective purchasers out of the market. It would appear that many of these tools have been produced from high priced labor and materials and the manufacturers are hesitating about taking their loss. The purchaser feels that in the near future he can purchase the same machines at a lower price and naturally postpones his purchasing. Then, too, many United States manufacturers of machine tools are using this opportunity to clean house, as it were, and are removing from their factory all surplus equipment and advertising same for sale. In some cases the tools thus placed on the market are in excellent condition and are very modern. A vast amount of machine tools of this variety is being offered, and compared with the prices of new machines they represent excellent value. Machine tool dealers report that they have about three calls for remanufactured and second hand tools, to one inquiry for new tools.

Small Tools and Supplies

Similar conditions to those reported last week exist in this line. All buying is of the small lot variety. The railways are deferring old work that is not absolutely necessary, and in this way have been able to reduce their purchases to a minimum. Other shops are following the same policy. The price lists are not very stable as yet owing to the liquidation of the many large firms that have found themselves to be overstocked.

Prices in non-ferrous metals have remained practically unchanged for the last week with very little business moving. The large cable companies manufacturing electrical cables are operating on short time and only parts of their plants, thus their purchases have decreased to a very small portion of their normal volume. The brass foundries, which in ordinary times, consume a large volume of scrap are practically idle and their demands are for small quantities only.

Pig Iron

The price of pig iron is up one dollar more this week. Orders from the Province of Quebec have been reasonably satisfactory, one firm alone having booked in the last week orders in excess of 600 tons. This is of course, only a nominal amount in the ordinary event, but goes to show that the small and medium sized foundries are operating and doing a fair business. No large orders have been reported as all the large foundries have not been operating for some time past. There is absolutely no call for scrap iron or steel and all the dealers have been forced to look elsewhere for a method of earning a livelihood. No doubt these men will reappear in the business as soon as business in this line improves.

PIG IRON SHOWS DECIDED INCREASE

Same Number of Blast Furnaces That Were in Operation During Month of June

The total output of pig iron and ferro - alloys in Canada during July showed an increase of more than two thousand tons over the production reported by the dominion bureau of statistics for June. Pig iron output remained steady at slightly over fifty-four thousand tons, but the production of the several grades varied considerably from the amounts reported for the preceding month. Of the entire output of pig iron over 90 per cent. was reported as having been made for the further use of the companies producing.

There were no changes during the month in the number of blast furnaces active, the six furnaces reported in blast at the end of June being kept in operation throughout the month. At the close of the month, therefore, six furnaces were active, namely, three at Sault Ste. Marie, one at Hamilton, and two at Sydney.

The output of direct steel castings of all kinds amounted to a total of 1,337 tons during July, a decline of more than 400 tons from the 1764 tons produced in June. Of the 1,337 tons reported, 865 tons were made for sale and 472 tons were used by the producers. The average monthly production for the seven months ending July of the current year was 50,000 tons. Output for the past three months, it will be noted, has been in excess of the average monthly production for this year to date.

J. C. Wilson & Co., Picton, Ont., have moved to Belleville, Ont., and are now to be known as the J. C. Wilson Mfg. Co. They have both a pattern shop and a machine shop. They make grey iron castings and brass castings, and in addition job steel castings. Machine work is often required on steel castings or they are included in order for iron castings or they are maintained a close connection with the steel foundry. The foundry is equipped for heavy floor work rather than for light bench and snap flask work.

NEW RE-HEATING FURNACE IS NOW IN OPERATION AT SYDNEY STEEL PLANT

THE new reheating furnace at the steel plant in Sydney, N.S. is now in operation. This installation, which cost $125,000 was completed in twelve weeks. Double shifts were used in the construction work, for the furnace was required quickly in order to complete a large rail order.

Before the new furnace was installed blooms from the blooming mill were carried direct on runways to the rolls of the rail mill, and put through while still hot from the open hearth. If anything happened to the rail mill rolls, the supply of blooms had to be stopped. If the stoppage of the rail mill was lengthy, the blooms naturally cooled and had to be laid aside. Moreover, the blooms got through the rail mill rolls at an uneven temperature owing to temporary delays en route.

This condition is now remedied. In between the blooming mill and the rail mill, comes the reheating furnace. Direct connection between the two mills is cut off. Instead of blooms coming straight to the rail mill and going through to the rolls on the heat retained from the open hearth, they are shot into the new furnace, reheated and delivered to the rail mill rolls as needed—every bloom at exactly the same temperature as every other, insuring an absolutely even grade of temper in the finished rails.

The Travels of the Bloom

The glowing red hot bloom is deposited on a steel carriage at the blooming mill and comes rattling down a minature railway line to the reheating furnace.

The furnace leads directly on to the conveyors leading to the rail mill rolls, and the bloom which comes down the track to the front of the furnace has to be deposited inside at the rear.

To effect this a twin set of rails, spaced widely apart, run along the side of the furnace from front to back. The bloom carried up from the blooming mill, is caught by rolls and dragged off the carriage. It is then seized by a pair of automatic clutches and dragged up the rails by the side of the furnace to the rear, where it is again caught by revolving rolls and run across the end of the furnace to a position directly in front of the door. The door is now

(Continued on page 56)

raised and the bloom is pushed inside by means of a mechanical pusher.

Delivering the Bloom

The interior of the furnace is heated by gas supplied directly from the coke ovens and is kept at an even temperature. When a bloom is pushed in at one end, it must traverse the whole length of the furnace before it comes out to the rail mill rolls at the other consequently it is thoroughly heated to the temperature of the furnace.

When the signal is given for the delivery of a bloom to the rail mill conveyor, the bloom rolls out through a heavy fireproof curtain at the lower end of the furnace, is caught by an endless chain conveyor and delivered to the rail mill rolls.

This new furnace will not only speed up the work at the Sydney plant, but will be a more economical proposition.

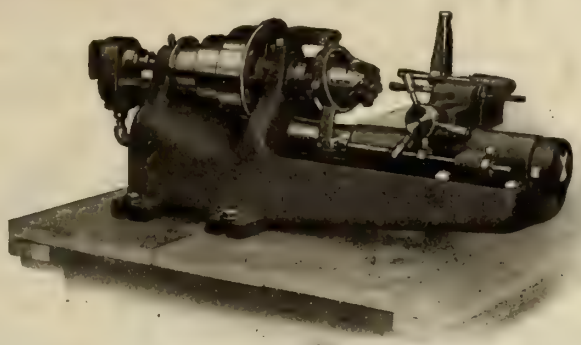
HUGE SHEAR

Many Features of Interest—Has Blades 30-in. Long, and has Cutting Capacity up to 6½ in. Square

Canada is going to be able to boast about the owning of another huge alligator shear. The new shear, which has been purchased by a well-known Canadian Co. will weigh 221,500 lb. when complete. It will be driven by a 120 h.p. motor, and the knifes in the shear will be 30-in. long with a capacity to cut 6½ inch square, or 4-in. x 24-in. cold soft steel.

The machine will have a cast iron bed, pitman, flywheel, motor base, etc., and cast steel lever, shafts, gears, etc., and all other subject to strain. The flywheel will be 11-ft. in diameter, and will weigh approximately 17,600 lb. The main gearing will have 15-in. face, and a ratio of 1 to 7½. When the flywheel shaft runs at 90 r. p. m. the speed of the shear will be 12 cuts per minute.

This machine contains various features, and it is equipped with a breakable pitman in the rear end of the lever which is so arranged that an overload will break the pin and probably do no further damage. The knifes are supported on cast steel knife seats, this distributing the load and preventing the crushing of the bed and lever. This arrangement also provides removable seats so that the bearing of the knife can be kept in better condition. The Garlock Walker Machinery Co. were instrumental in arranging for this machine to come to Canada, as they sold it on a special order.



COMMERCE COURSES WILL START SOON

The Queens University, Kingston, Ont., is starting a series of commerce courses for graduate engineers. According to those responsible for this special course, the need for such instruction has been widely felt and frequently expressed. The engineer is more and more called upon to undertake administrative and financial tasks. Native aptitude and painfully acquired experience have enabled many engineers to rise to these opportunities, but even for the exceptional man the way would have been much shorter had the alphabet of business been acquired in advance. For every Engineer some knowledge of business methods and business principles is becoming requisite. For the engineer whose interests and aptitudes fit him for the administrative rather than the technical branches of the profession, such training is particularly essential.

They feel that there is real remand and important field of usefulness for engineering graduates who have received, in addition to a fundamental training in science and engineering, instruction in business methods, business economies and business law. Business has gradually ceased to be a trade and is becoming a science. Employees, while having little difficulty in obtaining the services of men trained along specialized engineering lines, find it hard to secure assistants able to aid them effectively on the administrative side of their business. There is a growing demand for men familiar with the fundamentals of engineering and yet trained in the art and science of business.

The new courses will be open to engineering graduates of any Canadian University. Men with academic training in other fields, or with practical engineering experience, who may desire to take the work, should apply to the Registrar for special consideration of their cases. The University year begins on September 28th, 1921. Advanced students must register on that date. The Christmas vacation extends from December 17 to January 2. Classes close on April 19; examinations begin on Apri

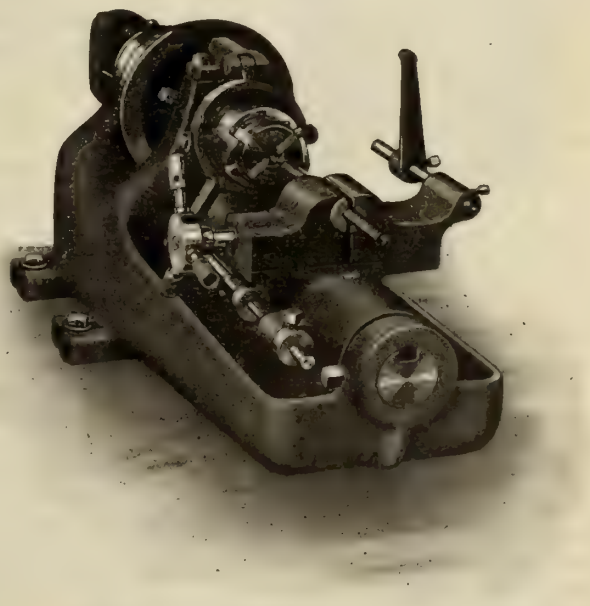
Geometric Bench Threading Machine

GEO MET RIC

Right in the Lead

With Another World Leader



This time it is---

The LITTLE BENCH THREADING MACHINE

The Geometric Bench Threading Machine is a wonder on small threaded work.

It weighs but 90 pounds and takes bench space of only 9½ x 29 inches.

The 5|16″ Geometric Rotary Die Head with which the machine is fitted cuts threads of standard and finer pitch on diameters 1|16″ to 5|16″ inclusive. The machine is arranged for bolting to a bench, or it may be mounted on a separate pedestal for floor use.

New Machinery Hall for the Toronto Exhibition

Should Present Plans Go Through Canadian Manufacturers Will Have a Modern Building In Which To Show Their Products—Such A Structure is Badly Needed

"A NEW Machinery Hall is needed badly at the Toronto Exhibition." Anyone who doubted this fact would have been instantly won over had they attended the meeting held in the board room at the Fair grounds on the evening of Sept. 9th, when several of the directors listened, and spoke to a delegation of machine tool manufacturers, dealers, and firm representatives.

The directors showed themselves in favor of the scheme. In fact they would have encouraged immediate action we feel sure, had that been necessary. Seldom has Canadian Machinery attended a meeting of so many branches of the machine trade that was in such complete harmony. The uppermost thought in everyone's mind was "We want a new Machinery Hall". It must be larger; be located in a better position than the present building, and above all it must be modern in every respect."

Mr. Irving, the director in charge of the meeting started the discussion by presenting briefly what the directors were prepared to do for the various exhibitors. He stated that he had long realised the present edifice was inadequate and he felt sure there would be little difficulty in passing the resolution for a new building through the board. Speaking on the financing of such a new building he said that exhibitors would be asked to sign a ten years lease guaranteeing the officials to occupy, or arrange for sub-letting their booths for that length of time.

Using the new "Pure Food" building as an example Mr. Irving explained that the exhibitors in this building would only pay a sufficient amount to cover the sinking fund and maintenance charges The same condition would hold good in the new machinery hall. Without entering into the figures he quoted, sufficient to say that he expected a charge of about 60 cents per square foot for space would be about right.

He mentioned that the directors were anxious to give exhibitors more value for their money. "I keenly realise" he said "that the present building is out of the beaten path. We even sent a band up the other day to play in front of the hall to attract attention in that direction. As far as I am concerned you cannot proceed too quickly."

At this point he brought in a rather novel and unlooked suggestion. He stated that if possible, the cost of such a new building could be considerably reduced by purchasing a factory building somewhere which was out of use. One of the Polson Iron Works buildings was mentioned, also some others throughout the country. The saving which could be effected was pointed out, not to speak of the speed in erection. The steel and brick work in such a building could be bought at the tonnage rate, torn down and re-erected in short order. Apart from the roof and floor, all other portions could be used.

One point which was brought out very forcibly during the meeting was the need of suitable lifting apparatus. The Polson building under discusion was said to contain one 10 ton, and one 25 ton crane. One member at the meeting suggested that he would like to see a 50 ton crane in place so that the various locomotive concerns could bring several of their engines for exhibition purposes.

The electrical branch of the trade also showed a great willingness to be among those present. It looks as if the term "Machinery Hall" will not be broad enough when the new building is completed for if the present plans go through the following trades, with possible additions will be represented:- Machine Tools of all kinds.

Wood working machinery.
Electrical machinery.
Machine tool supplies.
Electrical accessories.
Printing machinery.
Welding apparatus.
Boiler equipment.
Steam engineering equipment.
Mining machinery.
Mill supplies.

Molding machinery, and in fact every possible branch of the machinery industry.

After considerable planning, a committee was elected to look into the cost of building a new hall, the proper location, etc. Mr. T. A. Hollinrake of the A. R. Williams Co. will be president; Mr. McIntosh of the Canadian Manufacturers Association will be secretary, and the following gentlemen will also act on this very important committee:-W. Inglis of the John Inglis Co., General Engineers, Toronto; Mr. Ferguson of the John Bertram & Sons, Dundas; Mr. Blair of the Alfred Herbert Ltd.; Mr. Robinson of the P.B. Yates Machinery Co. Hamilton; Mr. Hamilton of the D.K. McLaren Co. Montreal and Toronto; Mr. Gaskell of Lancashire Dynamo and Motor Co. Toronto; Mr. Braden of the Canadian Westinghouse Co. Hamilton; Mr. Crowley of Davis Bournonville Co. Toronto; Mr. Waterous of Waterous Engine Works, Brantford; Mr. Alex Goldie of Goldie & McCullough Co. Galt; Mr. Bawden of Bawden Machine Co. Toronto; Mr. Patterson of the printing industry, Mr. Dobson chairman of the American Society of Electrical Engineers, also Mr. Hamilton, chairman of the American Society of Mechanical Engineers. Thus we have practically every branch of the engineering industry represented.

Faith in Canada

What the meeting lacked in the matter of faith was supplied by Mr. Murray who has had charge of the "Machinery Hall" for many years. "We have as good mechanics in this country as any other," he commenced, "and what is more I thoroughly believe that when we have anything to exhibit we should show it to the very best possible advantage." He also pointed out that without "Machinery" we would still be back in the dark ages. "Even the Fair would be impossible without the aid of machinery" he concluded. Mr. Murray struck just the right cord, for when the meeting dispersed to leave the committee alone to discuss their plans, groups of interested men could be seen outside discussing this, the most important move, that has been made for the good of the machinery trade in many moons. Among those present at the meeting were:—A. H. McQueen, Supt. Machinery hall; P. E. Thring, Bond Engineering Works; E. Kinrade, Dominion Belting Co.; J. Kaibs, Pullman Wiper and Waste Co.; W. S. Watson, Wayne Forge and Machine Co.; J. T. Donnolly, P. B. Yates Co.; J. S. Stewart, Canadian Link Belt Co.; C. W. Garner, Cleveland Pneumatic Tool Co.; P. H. Bradley, Elliott Machinery Co.; Mr. Ferguson for Pratt and Whitney and John Bertram Co.; E. F. Roberts, Dominion Steel Products Co.; P. A. Borden, Secretary of A.I.E.E.; Fredrick N. Moody of Powley and Townsley; W. J. Murray of Chapman Ball Bearing Co.; S. L. Montgomery and Mr. Smuck of the Prest-O-Lite Co.; C. W. Leslie, Toronto Battery Service Co.; G. L. Patterson of Miller and Richard; Ed. Logan, Clipper Belt Lacer Co.; W. F. McLaren, and W. S. Hamilton both of the D. K. McLaren Co.; Mr Hathwood, Prest-O-Lite Co.; E. E Clarke of the Clarke Electric Co., and J. M. Leslie of the Canadian Westinghouse Co.

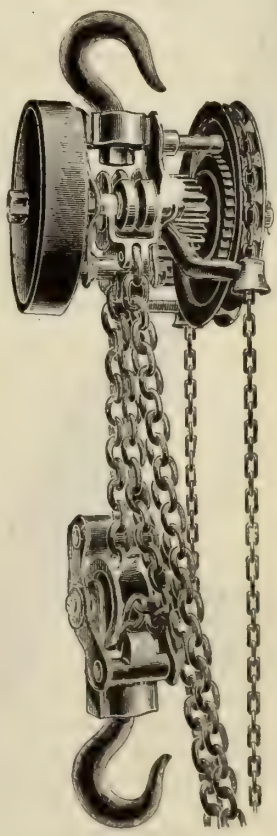
Everything in Fine Tools

Aikenhead's

The House that Sells You Quality

Wahlstrom Automatic Drill Chucks



Get the most work from your tools

Why? Because if you break the tangs on your tools you don't have to discard them or spend a lot of time in repairing. You can get just as much work—tangs or no tangs—if you use **Wahlstrom Automatic Drill Chucks.**

The instant-acting jaws of the **Wahlstrom** close on the entire shank and the grip becomes firmer and firmer as the resistance to the tool increases. Tools can be inserted and released in exactly **two seconds.** All tools are centered automatically.

Wahlstrom Chucks are mechanically perfect, true and strong with interchangeable parts. They are not limited to regular drill press work but may be used on boring or milling machines to spot, drill and ream without stopping the spindle.

Made in two styles—one for straight shank tools, the other for Morse taper shank tools.

Simplex 2-Speed Hoist

A Big Saver of "Man Power"

The too free use of "man power" for lifting and moving heavy machines can mean but one thing. Profits are slowly but surely slipping away! They can be guarded with a quick-acting, reliable Hoist—a hoist with capacities like the "Simplex."

The "Simplex" operates at two speeds. Small loads are lifted at twice the speed of large loads. The chains are properly guided so as to eliminate any tendency to jump the sprocket or stick in the guides.

Made in twelve sizes. Blocks with capacities up to 1,600 lbs. handled by one man. With blocks of capacities up to 40,000 lbs., two men can lift full load.

Aikenhead Hardware, Limited

Trade Gossip

The Palmer Steel Works at Jarron, England, have been reopened. Business generally in this district seems to be picking up rapidly.

* * *

The W. C. Hunt Brass Mfg. Co., Toronto had a fire recently which caused about $30,000 worth of damage. The fire was first found in the lacquering room, but efforts to stop the fire at this dept. failed.

* * *

The Russell Construction Co., Peterboro, have been awarded the contract for the erection of foundations, decks and hand rails for bridges numbers four and five at the entrance of the Toronto-Hamilton Highway. The contract was let after considerable discussion owing to the fact that the Blackwell Construction Company had tendered at $4,072 less. The successful company's figures were $43,375 and the Blackwell Company $39,303. The reason advanced for not giving the work to the lowest tenderer was that the controllers were not satisfied that they could do the job in the twenty-one days mentioned.

* * *

Arrangements for the opening and operation of the Government briquetting plant at Bienfait, Sask., are expected to be completed during the visit to Ottawa of Premier W. M. Martin and Hon. C. Dunning of Saskatchewan, who reached Ottawa recently. Premier T. C. Norris of Manitoba, is expected tomorrow to represent his Province. This plant was built at a cost of $680,000, for the purpose of manufacturing the low grade lignite coals of Southern Manitoba and Saskatchewan into briquettes for household use, the cost being shared by the two Provincial Governments and the Federal Government. Work at the plant will commence as soon as operating plans are arranged.

* * *

According to Reports the Canadian Pacific Railway Co. has placed a rather large order with the Algoma Steel Corporation. It is said that the order is for about 25,000 standard steel rails, and no contract price has been mentioned. This order together with those already on hand, will keep the corporations rail plant busy until November 1st.

* * *

Work has been commenced on the taking down and re-building of the trestle work for the Port Arthur blast furnace owned by the Palatine Mining and Development Co. Hancock & Co. are handling the construction work, and the same firm are rebuilding the bridges and culverts on the Pee Dee railway between North Lake and Gunflint to give access to the Polson mine.

* * *

The Preston Car & Coach Co. Preston, Ont., is going to be taken over by the Canadian Brill Co. Ltd. The new company intends starting operations immediately and has behind it the financial engineering and manufacturing resources of the J. G. Brill Company of Philadelphia of which the new company is a subsidiary. Operations will be started with a substantial volume of business, having orders on hand from Toronto and Winnipeg and the Timiskaming & Northern Ontario Railway, and the reorganization of the Preston Car & Coach Company will mean the bringing of considerable American money to Canada at once, and an increasing amount before long. All the work will be done in Canada, and it will mean an increase in the purchasing in this country, orders already having been placed with some Toronto firms.

* * *

The J. G. Brill Company of Philadelphia, the owners of the new company, is the largest company of the electric street railway car business in the world, and it also manufactures automobile bus bodies. The parent plant is operated in Philadelphia and there are other big plants at St. Louis, Springfield and Cleveland, and one in Paris, France.

The President of the new company is Samuel M. Curwen of Philadelphia, President of the Brill Company and all subdiaries; First Vice-President; H. K. Hauck, General Manager of the G. C. Pullam Car Company of Cleveland; Second Vice-President, A. N. W. Clare of Preston. H. D. Scully is a director and General Manager. Another Canadian director is yet to be appointed, as wel as two more American directors.

* * *

The new contract embraces the con struction of one thousand feet of new trestle, with 150,000 feet of timber, and the driving of 500 new piles as the in tention of the Palatine company is t have the entire work rebuilt with new timbers and new foundations.

* * *

One of the trestles, leading to the ele vator at the furnace, by which the lime stone and flux is delivered to the blas furnace, will be thirty feet in heigh and the other which leads to the roaste will be only twelve feet high.

COMMERCE COURSES

(Continued from page 52)

21st, anl last week or ten days. Co vocation for conferring degrees is he on May 10.

Instruction, after the elementary sta es have been passed, will be carried c as far as possible, by the problem met od. The aim is not merely to provi the student with the knowledge of bu iness methods and procedure, but to t him in thinking systematically on bu ness subjects and to develop his powe of investigation and analysis. Ea student is required to undertake a stu of some definite field of industry. limited amount of field-work will prescribed. Special lectures by bu ness men dealing with problems in th experience are being arranged. Fur er information can be secured by w ing the Registrar at the University.

Personals

. Home Smith has been elected chirman of the Toronto Harbor Commsion. Some consideration was given at he meeting, for the rebuilding of the os bition seawall, but a counter plan w presented which is now under consideration. Preliminary plans for the development of the eastern waterfront w approved, but detailed work can-nc be completed until the water lots at h Beaches have been acquired. It reported the dredge "Cyclone," wh has been in use on the Chippawa al, would be back in the harbor h tly.

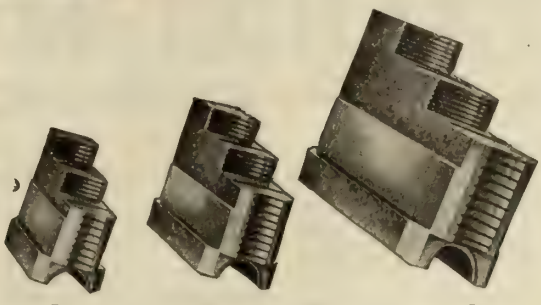
dvice comes from the Montreal field o e effect that F. W. Gray, editor of h Canadian Mining Journal, and asso-ied otherwise with the Editorial De-ament of The Garden City Press, St. e de Bellevue, Que., has been ap-oted assistant to D. H. McDougall, Vi-President of the British Empire l Corporation. Mr. Gray, who came Canada from England in 1904, was connected with the Dominion Coal o as confidential assistant to various e ral managers. In 1918 he became ant to the President of the Nova cia Steel & Coal Co., until his ap-o tment to The Mining Journal in the following year. Mr. Gray who is a well nformed and attractive writer on Can-d economics, is a member of the a dian Mining Institute.

* * *

Engineering

. W. McLimont, Vice President of the Winnipeg Electric Railway Co., has announced that arrangements have been concluded for the financing of a $10,000-000 power development project at Great on the Winnipeg River. Mr. Mc-t recently returned from a trip where he consulted with officials financial corporations.

When completed the plant to be de-ed will have a capacity of 168,000 power. Work on the project has begun and about 200 men now are ed. Later from 1,000 to 2,500 will be employed on the construction of the plant, which will be one of the world's largest systems for the development of electrical power. It is ex-ed that the project will be complet-1927.



The undertaking will be carried out the charter of the Manitoba Pow-mpany Ltd., which company is tak-the plant and assets of the Winnipeg River Power Company, Ltd. Manitoba Power Company, Ltd., Augustus Nanton, as President, will be surrounded by a strong directorate. A. McLimont will be Vice-President, the active management of construction operation will be in his hands.

Nesbitt, Thompson & Co., Ltd., investment bankers, of Montreal who will have associated with them several eastern banking houses, will finance the development. A. J. Nesbitt, who is head of the above firm, is also a director of the Winnipeg Electric Railway Company.

The production of pig iron and ferro-alloys shows improvement, according to the latest report from the Dominion Bureau of Statistics. During July there was an increase in production to more than two thousand tons, as compared with the month previous. There was a marked increase in the production of malleable iron during the month, the output rising from 661 tons made in June for sale to 2,922 tons made during July for use of the producing firms. Electric iron castings showed an advance over the previous month's record. The figures for the two months being 67 tons in June and 105 tons in July. Of the entire output of pig iron over 90 per cent was reported as having been made for the use of the companies producing.

Production of steel ingots dropped from 62,339 tons in June to 52,641 tons in July. Electric steel production declined from 1,276 tons in June to 608 tons in July.

INCREASE THE CAPACITY OF YOUR MERCHANT

There are two kinds of business policies of the merchandising field to-day.

The first believes the goods are sold when they have been sold to the merchant. Having bought the goods it is up to him to sell them and to get rid of them the best way he can.

The other thinks of merchants in terms of their capacity to sell his goods to the ultimate consumer, and having sold them to keep them sold and keep them coming back for more. The former very often finds new competitors coming into the field, and taking away a great deal of the business he has come to expect should be his.
The second approaches his merchant on a man to man basis. He encourages him to build. He shows him clearly and carefully what he is doing to help him create a market for the products he is distributing. Through the business newspapers the merchant reads, he shows him the turnover possibilities in his line. In fact, he shows him how to make more money for himself, and incidentally make more for the wholesaler or manufacturer.

The second and most successful type of business realizes that training does not stop when he has trained and sold his own selling forceon the goods he is merchandising. He realizes that this is only a beginning, that the great force of retail merchants who finally dispose of his goods to the ultimate consumer must be trained, must have knowledge, must have information, so they in turn can prove and sell the ultimate consumer.

The one great way to reach the merchants who are selling your goods is through the MacLean Trade newspapers, which merchants are reading every day and every week of the business year. They are reading them for new ideas, methods, for merchandising plans, for schemes to make more money. Now as never before they are studying the market pages and price quotations of every issue. Firms who are taking advantage of this avenue to better business are finding results far in advance of their expectations.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

TRADE K-T MARK

FOUNDRY

GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

OPERATED IN CONJUNCTION WITH A CONTINENT WIDE NET-WORK OF DISTRIBUTION STATIONS

"Liquid Air" Oxygen Means a Saving in Transportation

With a network of Factories, not only planned but in actual operation, and a number of Distribution Stations situated at all large centres all over Canada, Purchasers of Oxygen can obtain their supplies at a point very near to the point of consumption. This completely obviates heavy freight charges on cylinders and assures an immediate supply at any time within a few hours and even minutes after the orders are placed.

All cylinders conform to the specifications of the Canadian Railroad Board and are made to ensure safety without unnecessary weight. When purchasing "Liquid Air" Oxygen you not only save on freight, but in very many cases this expense is almost eliminated.

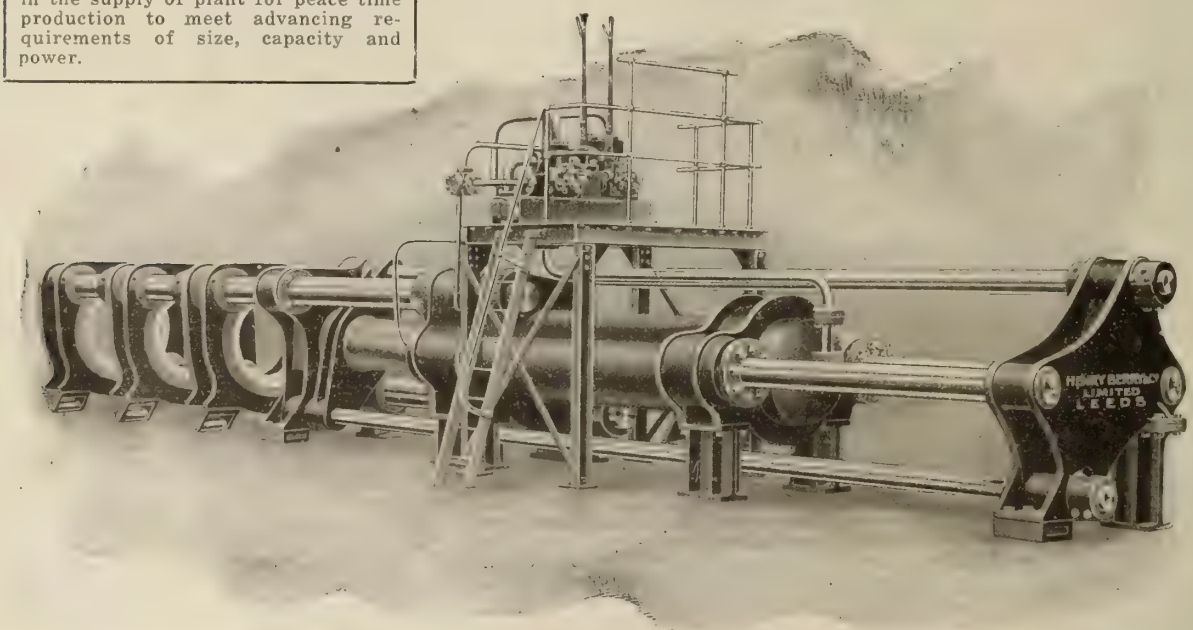
CANADIAN AGENTS:

Messrs. Fairbanks-Morse Company, Limited.

***Head Office*—Montreal**



A Cradle of Imperial Industry

Concerned for many years with the design and the manufacture of some of the largest types of machinery for the British Government, the Colonies and the Indian Empire, the firm of Henry Berry & Co. possesses some of the most extensive resources in the country for the production of the biggest, most powerful and most practical types of hydraulic machinery for Shipyards and Industrial Enterprises. These include all kinds of Shipyard Tools, Plates and Armour Bending Rolls, Rivetters, and Punching and Shearing Machines, Presses and Cranes.

Designs and estimates will be submitted to all requirements without charge. Prompt deliveries with full guarantee of Quality and Power.

750 TON PUNCHING & DRAWING PRESS

Pioneer manufacturers of hydraulic shell forging presses for the largest shells in use during the Great War, we are likewise always to the fore in the supply of plant for peace time production to meet advancing requirements of size, capacity and power.

All the Fine Qualities That Good Work Demands

Pratt & Whitney Small Tools enjoy an enviable reputation for excellence that has been well earned in the high production shops of the country. Where stamina as well as exceptional accuracy and precision are required P & W Tools have more than held their own. Our line is complete. It includes taps, dies, milling cutters, reamers, punches, drills, etc., both of standard and special design and in sizes to suit every requirement.

Prompt service is assured at our nearest store, where P & W Small Tools are carried in stock for immediate delivery.

Elimination of waste effort is the secret of complete efficiency--in a filing job as elsewhere.

A file that has lost its keenness wastes a workman's effort and time, and so costs more than a new file.

Keep a new file handy to replace the worn one, and for long-lasting efficiency specify one of these brands:

Kearney & Foot
Great Western
American
Arcade
Globe

Made in Canada by:

Nicholson File Company

Port Hope - Ontario

STRENGTH

Strength is a very essential quality in a wrench, but it does not depend entirely upon bulk or weight of metal. The strength and long-lasting qualities of Armstrong Wrenches are the result of skilled combination of the Best Steel, Expert Design, Accurate Machining, and Heat Treatment. All kinds and sizes.

The Waste You Can See is Least to be Feared

A HOLE in a dam or a leaky steam pipe is not to be feared; it cries aloud for attention.

It's the hidden leaks—such as excessive weight of pulleys on the bearings—air fanning and belt slippage that steal your power and add to its cost.

How to overcome these losses is explained in our book, "Getting Maximum Pulley Efficiency." Yours for the asking.

STEEL *for*
Every Commercial Purpose

We are the only company in Canada producing steel ingots by the "HARMET" Liquid Process, a process that makes these ingots vastly superior to the ordinary kind, improving the physical properties and reducing the waste of ingot.

We can supply forgings of all shapes and sizes made of ordinary or "HARMET" Fluid Compressed Open - Hearth Steel on the Shortest Notice.

Canadian Machinery's Used Equipment Service

IF you are in the market for used machine tools, electrical equipment, shafting, power equipment, etc., consult the "Used Equipment Section" of CANADIAN MACHINERY. It offers many opportunities in good used equipment and surplus stocks.

If what you want is not listed write us about your requirements and we will endeavor to put you in touch with possible sources of supply. Be sure to give details of what you want.

If you have anything to sell, the logical thing to do is to advertise it in our Used Equipment Section.

Our rates are reasonable and with white space goes service. If you want to test our service without advertising and without cost tell us what you have to sell.

CANADIAN MACHINERY & MANUFACTURING NEWS

"Used Equipment Department"

143 University Avenue,

Toronto, Ontario.

The illustration above shows the three protective coatings which provide an impregnable shield for the specially annealed steel which forms the core. An actual sample will be sent to you upon request.

Permanent Repairs

Now is the Time to Make Them

Manufacturing plants now need repairs. With winter snow, wind and storms approaching the need for renewing old roofs and siding becomes more urgent every day. Delays cost money.

This time make your repairs permanent. Why put on roofs that deteriorate quickly? The short life of unprotected metal shows that it is an unprofitable investment. To its short life add the cost of frequent painting and repairs and the evidence is even more conclusive.

This time use Robertson Process Metal. Rust and corrosion will be stopped. You end frequent repair work and painting. Your upkeep and maintenance costs will be cut to the bone and you will practice true economy.

Robertson Process Metal is a sturdy building material made in corrugated and flat sheets for roofing and siding. It is also made in building trim, gutters and other building details. It is protected by three impervious coatings (1) Asphalt, (2) Asbestos, (3) Waterproofing, which completely encase the steel sheet within. "Long life" is assured when your buildings are covered with Robertson Process Metal. Send for illustration and sample.

This partial list of users is significant because of the prominence of the various corporations and because all of them have used *Robertson Process Metal* repeatedly. Surely experience covering many year's usage is evidence of true value in the Robertson Product.

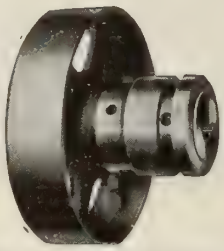
FOR PERMANENT ROOFS, SIDING AND TRIM

THE JOHNSON FRICTION CLUTCH



It's a Johnson Lineshaft Drive

A battery of twelve light presses, all on a bench about 30 x 5, driven from one lineshaft with Johnson Clutches controlling the machines.

Illustration by courtesy of The New Departure Manufacturing Co., showing bench presses in operation at their Elmwood Plant.

FRICTION CONTROL MEANS BETTER MACHINERY

We specialize in applying the proper type of friction clutch on any sort of an installation. Standard clutches available from stock, and special models developed to suit conditions.

COMPARE IT FOR FIRST COST

Twelve Clutches against twelve complete counter shafts, or twelve individual motors.

COMPARE IT FOR EFFICIENCY.

Quick, smooth control against the sluggish tight and loose pulley. Or one motor consuming current instead of twelve.

COMPARE IT FOR SERVICE.

You know the failing of belts—the continual attention they require, especially when they are shifted. If you don't know Johnson Clutch Service, just give it a trial.

Write for our booklet

"Clutches As Applied to Machine Building." and our Yellow Catalog.

Correct Lighting in your Plant means More Work and Better Work

Let Us Ease the Eye Strain

Good lighting is a factor of first consideration in any effort to improve workmanship, increase production, reduce spoilage and safeguard employees.

A poorly lighted plant breeds weariness and discontent, resulting in uneven production and waste. Ease the strain and get more and better work from a happier staff by installing a correct Industrial Lighting System in your plant.

Our illumination Engineers will gladly help in solving your particular lighting problem by planning the system that will most efficiently and economically meet your need. Such well-known names as Benjamin, Adams & Bagnall and Overbaugh and Ayres are included in our stocks of Illumination Equipment.

MANUFACTURING NEWS

VOL. XXVI, No. 12. September 22, 1921.

The Art of Drop Forging with Examples of Work

Blacksmithing And Drop Forging Are Widely Different—The Proper Design of Parts—The Question of Draft—Limits Usually Allowed—Producing of Intricate Shapes

CONTRARY to a popular impression, the art of drop forging is not merely a sort of glorified blacksmith's job. There is a vast difference between blacksmithing and drop forging. Each has its own field of usefulness therefore the two trades should not be confused.

The art of drop forging goes back about 70 or 80 years, although at that time the possibilities of the business were only being discovered. The bicycle really deserves the credit for bringing the art to a greater and better life, for when they were in vogue, small drop forgings were required for their manufacture. This condition induced the installation of small drop hammers running up to 1,500 lbs., with 2,000 lbs. as the maximum.

Next came the automobile, which in turn required large hammers, dies, etc., to speed up the necessary drop forgings for the different makes of cars.

The development of the art when bicycles became popular was nothing in comparision to that caused by the automotive industry, and it is due to the automobile that alloy steel has been developed to its high point of perfection.

Previous to the late nineties, little had been accomplished in the manufacture and heat treatment of alloy steels. With but few exceptions, Bessemer, open hearth, and crucible carbon steels were employed, and heat treating was a closed book to most people.

There is no difficulty in forging Bessmer, open hearth, and crucible carbon steels. Generally, these straight carbon steels flow much better in the dies, filling the impressions more readily than the alloy steels, and the daily product from them would therefore be higher—usually, very much higher. This difference in the rate of production is not always understood, although it is a very important factor in determining cost. Most of alloy steels are denser, more sensitive in character, require far more care in heating and forging and in addition to curtailing the output, necessitate special and accurate heat treatments, sometimes quite complicated, for which many drop-forgers are not properly equipped. Under these conditions the use of such materials has been discouraged to a certain extent. However, the meeting of these very difficulties by those who had the courage and determination to face them, has developed the drop-forging art far beyond its status of 10 or 12 years ago. Indeed the regulation of the various heats in forging, quenching and drawing induced by these alloy steels, made possible by the great advance in metallurgy, has placed the production of drop-forgings on a scientific basis.

Given proper equipment, there would now seem to be no reason, in connection with difficulty of production, why an experienced forging concern should hesitate to accept this business. So far as we are individually concerned, we have been successful in forging practically every alloy steel that has been offered including Nickel, Chrome-Nickel, Chrome-Vanadium and high Tungsten mixtures.

Copper and some of the bronzes, such as Tobin, Naval, Managanese, etc., can be forged but others, like Phosphor Bronze, cannot. Neither can Brass. Aluminum can be worked to some extent, if handled very carefully.

The Design of Parts

In designing parts for drop-forging it should always be borne in mind that the movement of the dies in the hammer is strictly limited to but one direction—the vertical. Undercuts and transverse-holes such as can be secured very readily in castings by means of cores, are practically out of the question in forgings. Attempts have been made in

Drop Forging an automobile crankshaft.

*Data and photographs by courtesy of J. H. Williams & Co., Brooklyn. N Y.

some cases to produce such openings by the use of mandrels so as to avoid finishing operations, but this method has never been commercially successful.

At one time, it was the practice to form the opening in the Lathe Dogs by use of mandrels. This system naturally required the use of at least two sets of dies and as many hammers. Before starting the job a stock of mandrels, which deteriorated rapidly in use—particularly the smaller sizes—was made up. This was an item of considerable expense in itself. The Dog was forged out flat without bend in the tail and with the opening formed, in the "break-down" dies; it was then trimmed, the opening punched and the tail bent. After the forging had been reheated, the mandrel was inserted and the Dog was turned at right angles to the previous forging plans and struck the necessary number of blows in the finishing dies. This operation removed the draft from the opening but at the same time threw out some surplus metal all around the edge of the hole. This was removed by a subsequent operation. Altogether it was a very slow and costly method of production and has since been abandoned.

Another instance of the attempted use of mandrels to form a hole, was the forging of wire rope sockets. It was thought that the tapered hole in the so called "basket" or hollow section of the socket in which the end of the rope is fastened, could be obtained by this method. The socket was first forged with the basket solid, but shorter and larger as its small end than its proposed final form. A straight hole about the largest diameter of the desired tapered cavity, was then drilled through the rudimentary basket; a tapered mandrel was inserted, and the attempt made to draw down the basket over this mandrel in a supplementary forging operation. After many trials the idea was abandoned. The basket is now forged solid and the tapered hole obtained by drilling and reaming. Much time, labor and money have been expended in other similar attempts to do by forging what should properly be accomplished by some other process.

Securing Additional Strength

Many pieces originally designed for castings are now made by drop-forging in order to secure increased strength without additional weight. In some cases the parts are not properly designed for the latter process and modifications in form are necessary before they can be produced. As the working of the metal during the forging operation automatically assures the absence of "blow holes," the increased cost of forging is considered of small moment in comparison to the certain removal of such possible defects.

In designing a part for drop-forging the necessity for "draft," or taper on its edges perpendicular to the parting line of dies, is not always fully realized by those not closely connected with the industry. It is a fact, however, that draft is absolutely essential to a commercial product if clean, smooth forgings are to be made. This taper is usually seven degrees. In deep, or narrow die impressions, or on odd shapes having a projection which must be "shot up" as it is termed, or forced into the impression in the upper die; the metal will not fill such a cavity so readily in the lower die, and in such cases 10 to 15 degrees of draft may be required. This increase in taper is often necessary also, at least to some extent, in holes or openings in forgings. These are formed by projecting "plugs" in the dies which generally require more draft than do the outside walls of the forging. This is so because the heated steel gradually cools during the process of forging and the metal in the forging itself contracts; consequently, it has a tendency, in shrinking, to stick on the die plug.

While it is possible to produce forgings with less draft than just cited, unless proper clearance is provided the dies deteriorate very rapidly indeed. Small cracks, technically termed "checks" which quickly grow larger and more pronounced, appear on the walls of the impression in the dies, forming corresponding projecting "fins" or thin slivers on the forging. These fins not only give the piece a very rough appearance but are often a positive detriment to holding the part properly in jigs and fixtures. There is no economy in attempting to decrease finishing expense by the reduction of draft only to create annoyance, delay and inaccuracy in machining, consequently increased cost.

Of course the regular daily product from such dies cannot be expected as the checks cause the forgings to stick in the impression, making it difficult for the operator to release the part readily from the dies while working. Furthermore, should less draft be taken than the best practice dictates, the very real danger of breakage, particularly where the impressions are deep, is intensified The expense of maintenance may be borne by the drop forging concern, yet if the dies fail, the customer is subjected to the annoyance and possible loss caused by the delay in replacement.

All these points are necessarily taken into consideration in estimating and pricing a job. In fact, so important is the question of draft considered, that it was one of the main reasons that led us to establish as our standard practice, the making of forging size drawings showing the exact degree and location of the taper for the customer's information before proceeding with the work. This matter of forging size drawing will be referred to later.

Another consideration that affects sometimes materially the question of design is the allowance or addition of stock to be removed by the customer in the finishing operations. We always recommend at 1/32 inch, even on small pieces where a machining cut is to be taken On larger parts this should be increased to 1/16 inch and on forgings like crank shafts 3/32 to 1/8 or more, depending on the character of the piece, should be added. These allowances for finishing are all in addition to such draft as may be necessary.

The Question of Limits

Regarding the question of "limits size." This expression can be taken two ways—(i. e.,) what is the minimum and maximun bulk or weight possible

A typical scene in a drop forging plant

a drop-forging, and, what is the closest to a given size to which it is possible to work. With equipment including hammers of the board-operated type from 300 lbs. to 3000 lbs. weight of ram and steam drops from 2500 to 3000 lbs. to 12000 lbs., we are producing a wide variety of parts both in our standard stock lines and in forgings made to the customer's order and design. The latter we call "Special Forgings." As might be inferred from the size of the smallest hammers just mentioned viz. 300 lbs.,—some of product is very delicate, quite a number of the pieces made in this equipment running 10, 12, or possibly more to the ounce. That is, 10 or 12 forgings would weigh one ounce.

Of course such parts can be made very fast as these light hammers operate rapidly and two or three forgings can be made at one heat. This is accomplished by working from the end of the bar steel, or other metal, instead of cutting it up into pieces suitable for the individual forging. The bars are cut to lengths convenient for handling—say about 3 feet—and the end is heated and forged. The forging is then severed from the bar by means of a "cut-off" attached to the hammer and another forging is made without reheating. This process can be repeated as long as sufficient heat is retained in the bar, but as the metal cools rapidly, two or three forgings are about all that it is safe to work before replacing the stock in the furnace. It is always more convenient to work from the bar, instead of using tongs, but in making heavy or larger parts this is not practicable and consequently the stock for such pieces is cut to length suitable for each individual forging.

Usually small parts require only one forging operation, and can be made fairly close to size—say a variation in thickness of 1/64 or 1/32 inch, depending on the shape and the size of the piece and the kind of material used. If greater accuracy is required they are sometimes restruck cold after they have been trimmed. This operation may be performed in the forging dies, or in separate striking dies made especially for this purpose. Type bars for typewriting machines are usually put through this process, so that the variation in thickness will not amount to more than a few thousandths of an inch. As the forgings increase in size they usually vary more both in thickness and in length. Connecting rods for gas engines are a good example of this tendency. Their typical design includes a large boss on either end connected by a thin shank of I beam section, the larger boss usually having a hole formed in it. On parts of this class, with a centre to centre distance of say 10 inches, a variation in the thickness of about .14" should be expected. In length the variation will run plus or minus 1/32 inch. Crankshafts being larger will show greater difference. For instance, on a four throw shaft about 43 inches long for an 8 cylinder motor of about 150 h. p. 3/32 inch variation in thickness, and plus or minus 1/16 inch in length would be required. Many larger parts are now being produced in the drop-hammer that would have been absolutely impossible only a few years ago, with the smaller machines then in use.

Showing a set of dies for automobile work.

With this increase in the size of forging equipment has come the possibility of enlarging the dies also, particularly in length, so that the manufacture of long pieces like automobile axles and six-throw crankshafts is now taken as a matter of course. In the old days, even a four-throw shaft was a very serious proposition and an axle was a fearsome undertaking. At this point, although the matter is not directly connected with the question of size, it may be of interest to refer to a great advantage possessed by drop-forgings as compared with hand work. By this is meant the preservation of the direction of the natural grain of the steel. Because of the bending provided by the preliminary operations in the drop-hammer, the fibrous structure of the bar stock in crankshafts, is continuous throughout the entire length of the forging-bearings, arms and wrist pins. In hand work under the steam-hammer, however, such continuous grain is impossible as the parts are made by drawing out the end bearings or shaft-ends, leaving a slab or chunk of solid stock from which to form the arms and wrist pins by machining. The metal between the arms is then removed, leaving the arms themselves with the grain of the steel running transversely to their length. The strength and stability of the entire crankshaft are undoubtedly adversely affected by these short-cross grains in the arms, although of course test pieces taken from the shaft ends, in which the original structure of the steel has been preserved, would not indicate the lower physical properties of the arms. The continuous grain of steel in a drop-forged crankshaft is shown very clearly if the part is pickled excessively.

The largest drop-forging of which I have heard was a traction engine, two

Producing crank shafts at high speed

cylinder crankshaft about 6 1/2 feet long with wrist pins and main bearings about 5 inches diameter, and rectangular arm sections about 4 by 6 inches. The weight of the forging was approximately 570 lbs.

Axle forgings will vary similarly to crankshafts, both in thickness and in length, so that proper allowance to care for this matter must be made in sinking the dies so as to enable the customer to secure a clean, finished surface by his machining operations. In considering the matter of variations, it must always be remembered that drop-forgings are not machine work, i. e. they are not produced by cutting tools such as millers, planers, boring-mills, etc., from which extremely accurate work can be obtained. The process in its final analysis, is really "machine blacksmithing" and consequently variations such as have been referred to, are absolutely necessary and must be expected. Although the die impressions are sunk very accurately to size, they will naturally wear in use, so that after they have made a few hundred or a few thousand pieces, as the case may be, they will have become enlarged to a greater or less extent. The amount of this enlargement denends upon the hardness of the die blocks, the difficulty of forging, the particular piece involved, and the material used. For instance, carbon tool steel must be worked at a lower forging heat than is permissible with so-called "machine steel" of either Bessemer or open hearth grade. In addition to being naturally "harder" than the two latter because of its higher carbon content, the lower temperature at which tool steel is necessarily worked in the drop causes an appreciable increase in the rate at which the dies deteriorate: consequently, other things being equal, forgings of this or other material that, for one reason or another, is difficult to handle, will tend to a greater variation in size than will parts made of the softer steels.

Producing of Intricate Shapes

Considering the restrictions imposed upon the production of drop-forgings by the application of only vertical blows with the part in a fixed, predetermined position established by the lay-out of the dies, it is surprising what can be accomplished in the manufacture of really intricate pieces. In producing many such parts the entire striking surfaces of the dies do not meet on a flat, horizontal plane, although there must always be a sufficient area of flat surface to absorb some of the force and shock of the hammer blows. Tools with such irregular meeting faces are technically called "locked dies" irrespective of the amount of this irregularity which naturally varies considerably, some dies showing merely a slight bend or inflection from the horizontal, while in others the "lock" may be several inches deep. Two instances familiar to all of us may be given to illustrate the use of such tools.

One of the steering arms attached to the steering-knuckle of an automobile is usually made somewhat in the shape of a letter Y with arms curved for clearness and the ends seldom if ever, on the same plane. Sometimes the difference in the height of these various ends is considerable. Of course, the part could be forged flat and then bent to shape, but so long as the quantity warrants, as it usually does, nowadays, it is better practice and cheaper in the end to make the more expensive locked dies to produce the desired angles and offsets, thus, avoiding the supplementary operation of bending. This is true also of many pieces that were previously forged flat and then bent to final form either by hand or by special tools in a press or hammer.

The second instance of the use of locked dies is that of lathe dogs to which reference has already been made. In order to produce the bent tail typical of the pattern in use in this country, the piece was tilted up and the dies so constructed that the bend in the tail comes in the bottom of the lock which resembles the letter Y with its arms opened or spread apart at the top. The introduction of this method of manufacture also made it possible to eliminate draft on the walls of the opening in which the work to be turned is held when the "dog" is operated on the lathe.

An interesting way of securing the seemingly impossible in a drop-forging is to forge and trim the piece complete, then with the part turned at an angle to the first plane of production, put it through a second and distinct forging and trimming operation. An example of this method of working is that of Eye Hooks with the eye at a right angle to the hook portion. To produce this result, the hook is forged with the hook portion in its final form but with a solid lump of stock for the eye. The latter is completed in a second forging operation. When parts are made as just described they have a tendency to vary more in length than is usual in forgings of their size which are produced in a single set of finishing dies.

Lamp brackets for automobile headlights require more than one operation to produce, and considerable ingenuity has been displayed in their manufacture. The problem, of course, is to distribute the metal properly and economically in the preliminary operations. One method is to forge the entire piece with the two arms straightened so as to come fairly close together—say a couple of inches apart. After trimming, the arms are spread and bent roughly to the final shape; the bracket is then completed in the finishing forging operation. Another way of producing these pieces, is to form the arms roughly from a piece of flat steel in a cold operation, then bend approximately to shape after which the entire bracket is forged as in the final operation of the first method.

The various illustrations throughout the article will give readers an idea, not only of how crank shafts are forged, but also the dies necessary in the making of an automobile drop-forging.

Before closing we believe a word should be said regarding the person responsible for the management of a drop forging dept. He should be, to our mind, a trained engineer, one who understands the capacities and capabilities of the plant under his control, and he should possess a practical knowledge of metallurgy. He should understand steel and its heat treatment, and he should be gifted with a live imagination as he will need such an asset to cope with the many and varied problems he will meet from time to time. We could go on indefinitely speaking of an ideal drop-forging plant manager, but we have already proved our point, viz, that a drop-forging is not a glorified blacksmith's job, but is indeed an art.

PREVENTING AMMMONIA LEAKAGE

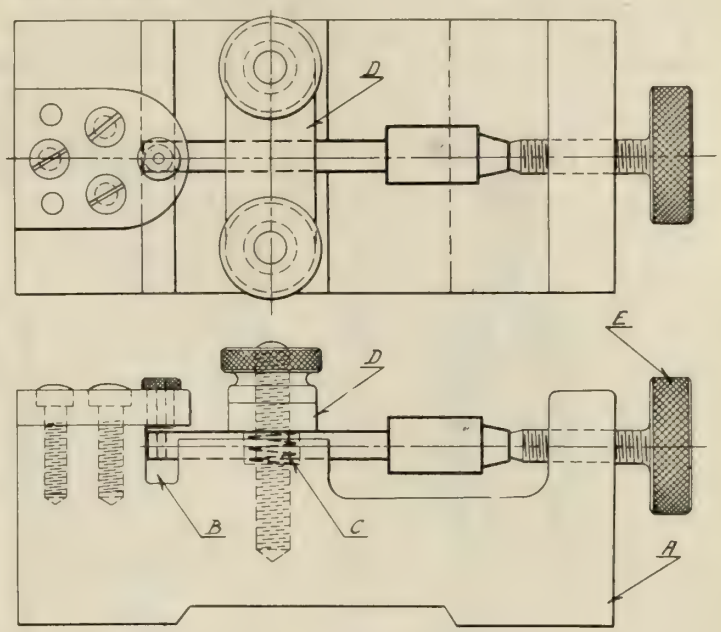
The advantage of permanence, lower cost, and ammonia saving, gained by eliminating joints in ammonia pipe coils by Thermit welding as compared with installing ammonia flanged connections is being appreciated according to reports by the Linde Canadian Refrigeration Company, Montreal, Que., which handles refrigeration machinery for industrial plants and ships.

Since adopting this pipe welding process in 1918, the company has ordered material for welding in the neighborhood of fifteen miles of 1¼ inch extra heavy steel and wrought iron pipe for refrigeration units installed in a large number of industrial plants. The length of coil used varies from 500 to 5,000 feet. The whole coil is made up in sections of endless pipe. These sections are flanged and bolted together on the job. The sizes of the sections vary from 6 feet to 36 feet in length, and from 3 pipes high to 20 pipes high. There is one weld for every 20 feet of pipe used. No screwed fittings are used on any of these installations, but instead the pipe is bent to suit, and male and female flanges are connected together using a lead gasket. The coils are flanged before being shipped and tested to at least 150 pounds hydrostatic pressure test. In very few cases has it been found necessary to cut out a weld.

NEW PAPER MACHINES

The Laurentide Co., at Grand Mere, Que., have recently installed two new 166-in. news machines. This means that they will be able to produce marketable paper at the rate of at least 1,000 feet per minute. The machines have a daily capacity of 75 tons each, and were made in Canada. The Dominion Bridge Co., built these machines.

Making Back Gear Parts for Milling Machine

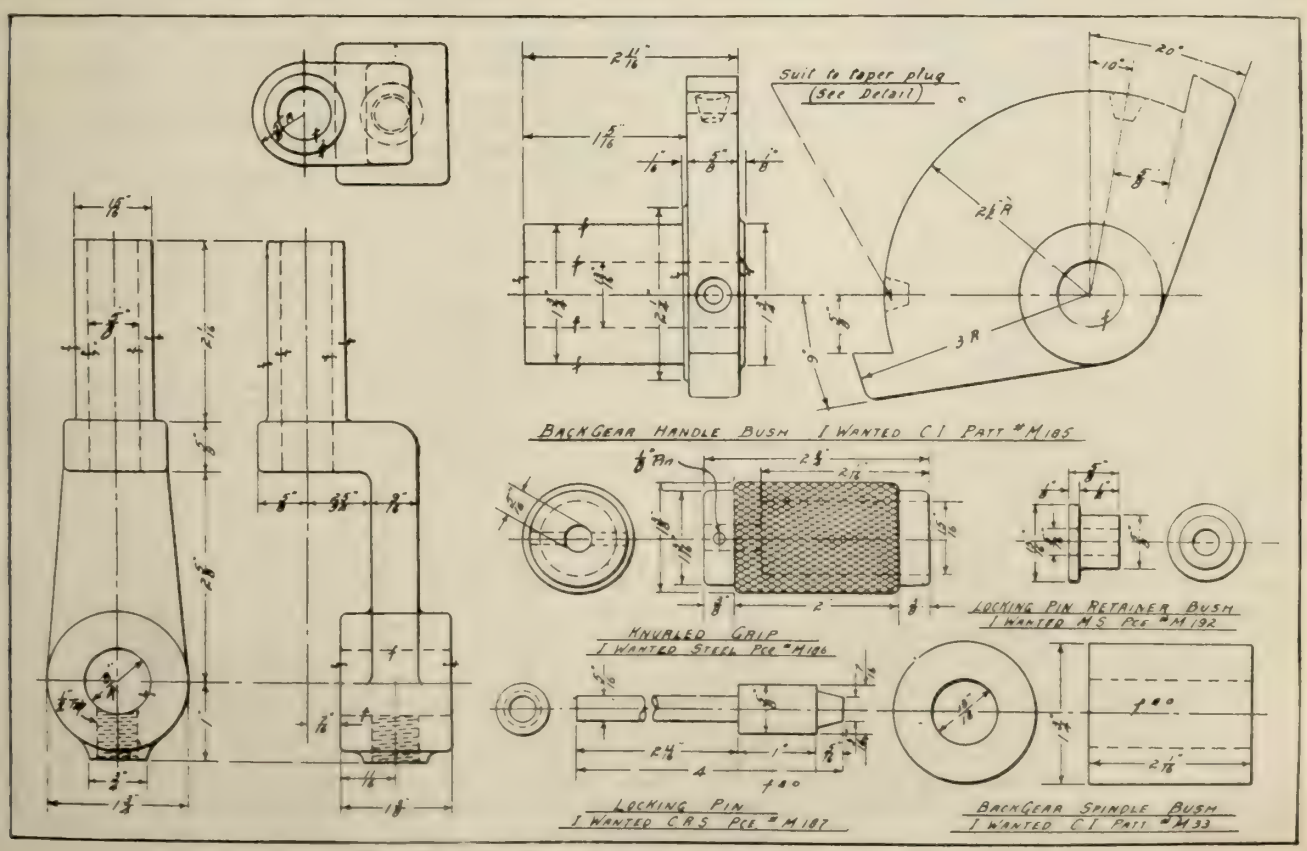


Operations on Back Gear Handle Quadrant—Three Are Required—Machinery of Spindle Bush—Back Gear Levers—Locking Pin—Retaining Bush and Knurled Grip—Rate of Production Given In Each Case

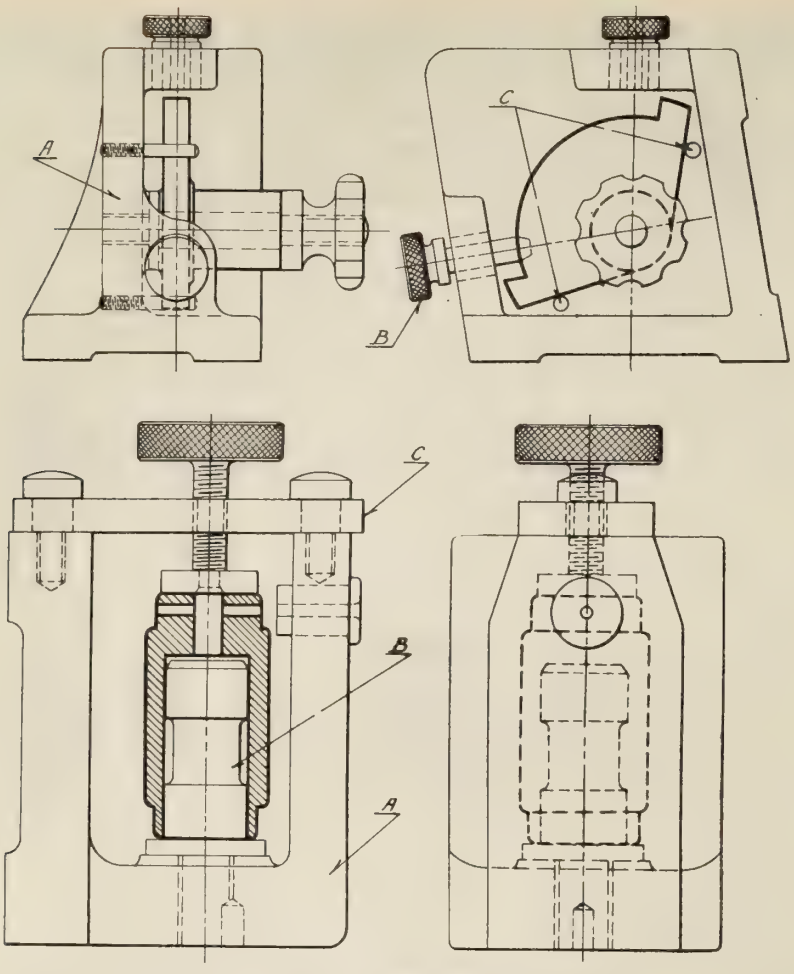
By G. BLAKE

FOLLOWING up the article on the making of back gear parts which appeared in the Nov. 25th, 1920, issue of Canadian Machinery, here are my views on the subject, taking the parts one by one. First, we shall consider the back gear handle quadrant.

Back Gear Handle Quadrant.



Three operations are necessary on this part. First, grip the piece in a three-jaw chuck, drill, bore and ream to 13-16 inch diameter, and face the boss. The quadrant is then placed on an arbor for the turning of the outside diameter and facing the opposite end. For the third operation a drill jig is used. The body A, is of cast iron, and the work is held in position by the two pins C, and locked on the supporting pin by means of a knob screw. A 5-16 inch drill is first entered to the required depth, after which the slip bushing is removed and a taper reamer used to complete the hole; a stop collar being fastened on the spindle to obtain the proper depth. When the first hole is reamed, a special stop pin is inserted while the second hole is being drilled and reamed. The production on this particular piece is six, eight to ten pieces per hour respectively, for each operation. The approximate cost of the drill jig will be $110.

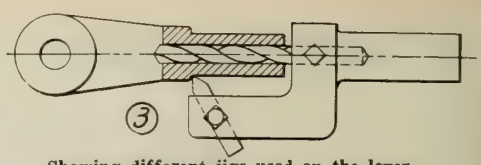


Jig used for drilling locking pin.

Spindle Bush

Next we come to the spindle bush. The machining of this piece does not

The group shows the parts which are under discussion.



Showing the jigs used for back gear handle bush and knurled grip.

call for any special equipment. Use the knee tool for rough drilling and turning (the same as is used on the back gear lever). The making of this bushing is a simple capstan job, machining to the dimensions given. The capstan operations give a production of 5 pieces per hour, while the removal of the burrs after cutting off is done at the rate of 40 per hour. Specialized labor is used.

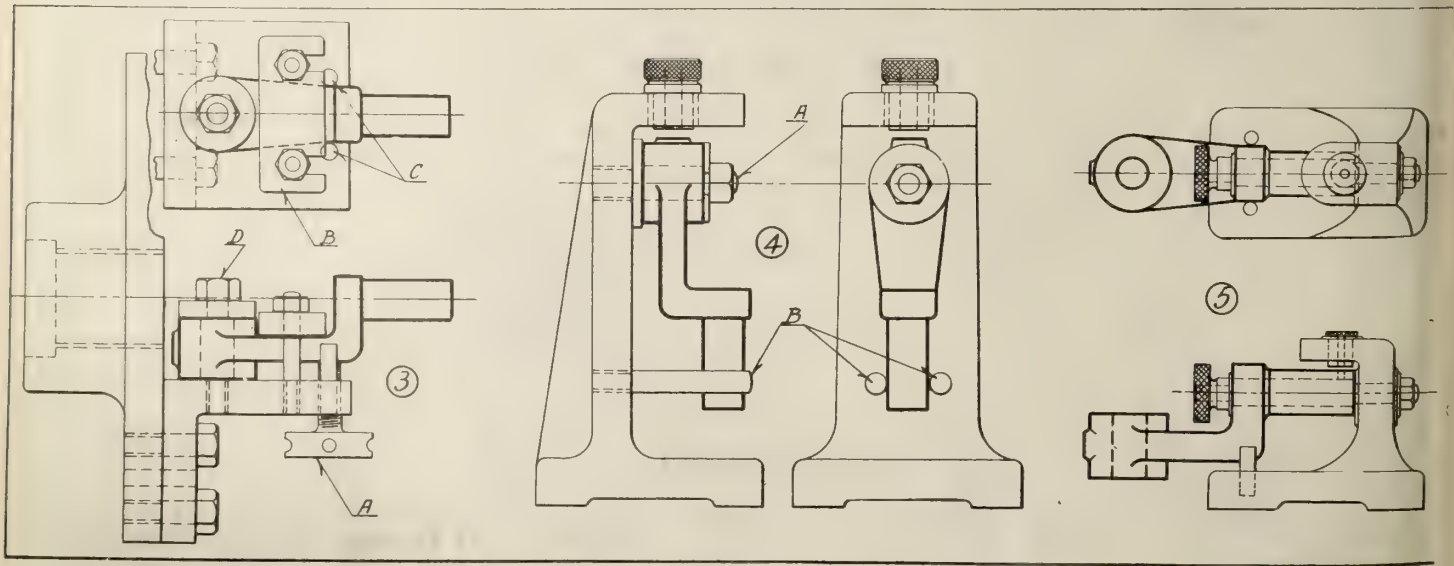
Back Gear Lever

The machining of back gear lever is performed as follows: The rough casting is gripped in the capstan and the hole in the boss drilled, bored and reamed to a diameter of three quarters of an inch, with the allowable tolerance. The inside face of the boss is faced off at this setting. The piece is then placed on an arbor, and the opposite side faced off so that the boss has an overall thickness of 1 3-8 inches. The lever is next located in a special fixture secured to the face plate of the machine, as shown at (3) and so arranged that the inside face of the boss is 7-16 of an inch below the axial center of the cylindrical portion. The outer end of the lever is supported by the adjusting screw A, after the lever has been securely fastened to the angle plate.

Showing different jigs used on the lever.

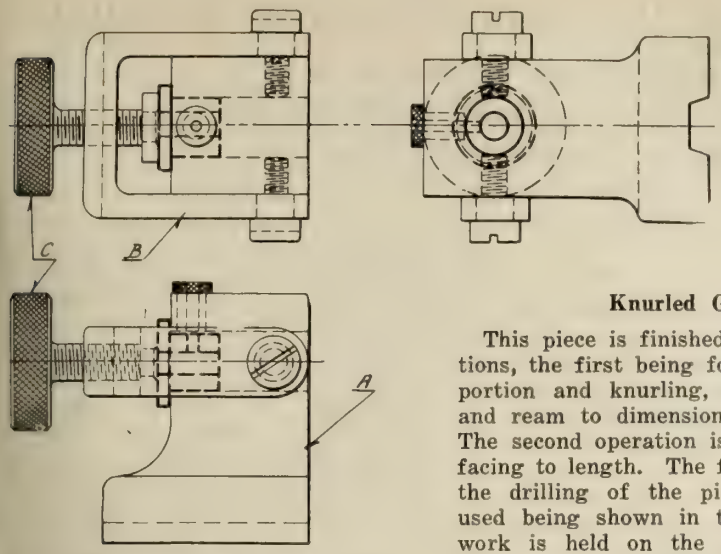
In addition to this support below the lever, it is held in proper alignment by two small pins C. The cross strap is bolted down on the work after all the other clamping has been performed. The angle plate is held to the face plate by means of four cap screws and two dowel pins. The outside diameter of the cylindrical portion is turned at the same time as the hole is being drilled, by means of the tools shown in the small sketch (3a).

The hole for the half-inch set screw is drilled and tapped in the fixture shown at (4). The two pins B, align the lever in a vertical position and prevent it from moving while in the fixture. The slip bushing is removed after drilling, so that the tap has a free entrance. The small pin hole in the turned portion is drilled in the jig shown at (5). The machining for the lever are as follows:



1st operation 12 pieces per hour, on capstan.

2nd operation, 15 pieces per hour on central lathe.



3rd operation, 4 pieces per hour, on capstan.

4th operation, 15 pieces per hour, on drill.

5th operation, 35 pieces per hour, on drill.

Showing turning of outside lever.

Drilling jig for locking pin retainer bush.

Using specialized labor on all operations, the cost of the fixture for the third operation would be from $90 to $125, and the knee tool $45 to $60. The cost of the jig for the fourth operation would be from $65 to $85, and the cost of the jig for the fifth operation from $55 to $70.

Locking Pin.

The first operation on this piece is accomplished on the capstan lathe, the details being, rough and finish turn 5-16 inch diameter, form taper and part off. The piece is then rechucked and the tapered end faced off. The last operation is the drilling of the small hole in the end of the straight portion. The jig used on this operation consists of a body A, made of cast iron, with a V-groove for supporting the work. The slot B, at the end is for the cuttings to get away. The clamping plate D is held by two knurled thumb nuts. The springs C, are for supporting the clamping plate when the nuts are released. The relative production times for the three operations are six, forty, and thirty pieces per hour. Specialized labor on all operations. Cost of the drill jig will be about $60.

Locking Pin Retaining Bush

This is a straightforward job on the capstan lathe; rough and finish 15-16 inch diameter, and likewise the 5-8 inch portion. The hole is then drilled, bored and reamed to size, after which the piece is cut off, leaving a little for facing off in the next operation, which is done by rechucking the bush in the capstan chuck. The drilling of the small hole in the side of the bush is performed in the jig shown. The body is of mild steel, the swinging bridge carries the locking screw, the washer on the end of the screw C being of the revolving type to prevent injury to the work. The rate of production will be as follows: First operation, 12 pieces per hour; second operation, 35 pieces; and the third operation, 40 pieces per hour. The cost of the drill jig would be about $45.

Knurled Grip

This piece is finished in three operations, the first being forming the outer portion and knurling, then drill, bore and ream to dimensions, and part off. The second operation is rechucking and facing to length. The final operation is the drilling of the pin hole, the jig used being shown in the sketch. The work is held on the pin B, and the screw in the swinging strap C, locks it in position. The washer revolves on the end of the screw to prevent scratching of the work. The rate of production is as follows: Four, thirty and thirty-five pieces, respectively, for the first, second and third operations. The jig cost will be about $60.

EXAMPLES OF CAST IRON CUTTING

Instances indicating the value of cast iron cutting as an economic factor in industry continue to multiply. The following cases are fairly typical of its emergency uses:

The superintendent of a large Indiana manufacturing plant, asked if he ever had occasion to cut cast iron, replied in the negative. In his opinion, it might be an entertaining stunt, but he saw no practical utility for the practice in his plant. Curiously enough, a few days later, in remodeling some of the powdered coal furnaces in the power plant, it was found that the cast iron floor plates for the upper deck were several inches oversize and would have to be cut off. The plates had been hoisted and bolted into position at one end before it was discovered that the other ends extended over instead of resting on the centre of the supporting "I" beam. The attempt to correct the fault by cutting off the excess lengths with drilling tools proved very slow work. After two and one-half days of continuous drilling, during which time gangs of brick masons and machinists were forced to wait in idleness, and only two of the four plates had been cut, the superintendent ordered a cessation of the drilling and asked the aid of oxweld operators to complete the job.

Using a standard oxweld type C-6 torch they cut the two remaining plates in one hour and forty-five minutes. The work was done so accurately that the finished plates were found to line almost perfectly with the centre of the beam. The plates were 1¼ inches thick and 60 inches long, the operation consuming 310 cubic feet of oxygen and approximately 100 cubic feet of acetylene. An interesting feature was the fact that the cutting was effected directly over, and without injury to, the beam.

Another demonstration was recently made at the works of a large Pittsburgh foundry where some heavy iron castings were cut by oxweld operators. It may be of interest to note that the acetylene for this job was furnished by a low pressure acetylene generator, and that, owing to the use of an oxweld type C-6 blowpipe it was not necessary to preheat the work, excepting as this was done automatically by the multiple jet flames of the blowpipe in pursuing the prescribed cutting manipulation.

BRITISH TURBO-ELECTRIC LOCOMOTIVE

Great secrecy is being observed regarding the turbo-electric locomotive which a leading British engineering firm is building for trial on a main line British Railway. It can, however, be stated that the principle adopted is similar to the system of electric ship propulsion which was first patented in Great Britain. The prime mover is a high speed turbine coupled direct to an electric generator; this generator supplies current through controllers to motors which drive the wheels through some form of gearing. The advantage of this arrangement is that it combines the great efficiency of the high-speed turbine with the flexibility of electric speed control. If the trials are successful they will probably lead to the conversion of many express steam locomotives to the electric drive. This turbo-electric locomotive is not to be confounded with a new type of "thermo-electric" locomotive which another leading British firm is building for experimental purposes. In this case the prime mover is an internal combustion engine of a novel and economical design, which can utilise any kind of crude oil. In countries where there is a deficient water supply along the routes of railways there is a good field for an internal combustion engine locomotive which proves to be really efficient.

TWO HINTS ON DIFFERENT SUBJECTS

By D. A. H.

If called upon to make an automobile axle or drive shaft in the smaller sizes, say 1-1/8 inch and under, and a length of axle steel cannot be located, the best material to use is a piece of chisel steel or drill steel. This is obtainable everywhere, it is a carbon steel of requisite strength, unannealed but soft enough so that it can be turned where necessary.

Planer driving pulleys of the larger sizes develop a rumbling, rattling noise as they wear looser and they thus get a chance to slap as they run. Circles of heavy pasteboard cut to fit inside the rim and applied to the inner and the outer pulley will greatly deaden this noise.

Improvement Necessary in Locomotive Design

Constantly Growing Passenger and Freight Traffic Makes Problem for Locomotive Designers—Efficiency and Capacity Should Be Increased—Labor Saving Devices Necessary.

By H. W. SNYDER

NO one, it is believed, will dispute the fact that the present-day operation of high-power locomotives is one of the most vital questions with which our railways are concerned. The demands of constantly increasing passenger and freight traffic have brought about a constant increase in size and power of aur locomotives.

It has not been so many years since an engine of 25,000 or 35,000 lb. tractive power was sufficient to take care of all requirements. Twenty years ago cylinders 22 or 23 in. in diameter were considered as about the limit in size. Constantly increasing demands on motive power since that time have brought us to the huge Mallet engines with tractive powers of from approximately 150,000 to 175,000 lb. Our simple engines have increased from 20-in. or 21-in. diameter cylinders up to 31-in. cylinders, with a tractive power ranging from around 35,000 lb. to 83,000 lb. In view of the rapid strides that have taken place in increasing the size and power of locomotives within the last few years, it seems rather out of place to predict that the maximum has been reached. It is also true that the use of improved devices has made possible the satisfactory operation of the large locomotives of to-day. Everything seems to indicate that we have not reached the maximum capacity of the locomotive even within the present limits of clearance and rail load, and we may expect to see these same engines made far more powerful and economical by the application of devices which are now available or which are already being given serious attention.

In view of the foregoing, the most vital matter which confronts locomotive designers and operating officials is that of increasing the capacity as well as the efficiency of the locomotives which we have to-day, and in the following paragraphs an attempt will be made to draw attention to some of the problems involved and upon the proper solution of which depends their success.

Combustion and Steam Generation

In order that large engines may operate properly, it is of course necessary that a sufficient supply of steam be furnished to cylinders so that they can be made to produce their maximum horsepower. It is not enough to provide a given number of square feet of heating surface in the firebox and the tubes—it is necessary that we take into account proper construction of the boiler, necessary firebox volume to produce the best possible combustion of fuel, and the design of grates so that fuel will be economically burned to such an extent only as required by the maximum evaporation of the boiler.

In producing heavy motive power it has been necessary on account of prohibitive axle loads to apply a sufficient number of axles under the engine to reduce the individual axle load to within reasonable limitations. This has lengthened out the engine to such an extent that boiler design and maintenance have become a serious problem. In the first place it is necessary to design a boiler that will properly function with the other vital parts of a locomotive. At the same time the length has become such that the use of combustion chambers is a necessity to avoid a prohibitive length of tube. Large engines have been constructed with a tube length of 25 ft. and it seems that no definite rule has been established as to what the limit of length of tube of a given size should be. Tubes 2 or 2¼ in. in diameter in excess of 20 ft. in length however are questionable, and this feature should be looked into carefully before a decision is reached.

The application of a long combustion chamber requires a large number of additional staybolts, and it would naturally be expected that a boiler of this kind would require more staybolt attention. Complete as well as partial installation of flexible staybolts has met with varying degrees of success on many railroads, but the consensus of opinion seems to be that their application goes a long way toward overcoming staybolt trouble. It has been proved by experiment that if flexible stays are properly applied to the boiler when built, while they may make a slight movement during the firing up of the locomotive, after the boiler has become completely heated and steam pressure raised these stays assume their original position. Although long combustion chambers require more attention in maintenance, this will be offset by the increased firebox volume and the resulting better combustion.

On account of height limitations, the height of the dome as well as the steam space in the boiler has been reduced to such an extent that difficulties are being encountered with the proper life and maintenance of superheater equipment, because too much water is drawn over through the throttle into the superheater. This is a question requiring experiment to determine as nearly as possible the minimum steam space which should be provided for boilers working on various grades. The height of the dome has a great deal to do with obtaining dry steam, and in the opinion of the author consideration should also be given to the height of the throttle above the water line as well as to the steam space in the boiler. Considerable development on this subject is now well under way and we can confidently expect results of value in the near future.

We have about reached the limit of size of cylinders and size of boiler due to road clearances, and to undertake to provide additional road clearance on practically all of the main lines to-day would mean a total expenditure of money entirely out of proportion to the benefits that would accrue.

On account of the apparent limitations of piston thrust and road clearances, the greatest problem we have with our large locomotives to-day is to increase their capacity without exceding greatly our present sizes. Anything to increase the hauling capacity of the locomotive without increasing the height and width limitations under which the locomotive must work might be called an essential capacity-increasing device. A few of these with which we are most familiar and which have proved beyond doubt their desirability are the superheater, the brick arch and the mechanical stoker, There are possibilities of still further increasing the efficiency of the superheater without increasing the size of the boiler in which it must operate. There are also possibilities and constant improvement in the design of brick arches which lend to higher evaporation and better combustion of fuel. It has been stated that when a locomotive requires as much as 6,000 lb of coal per hour it has gone beyond the limits of the ordinary fireman. Automatic stokers have been in use so long

Points Brought Out

In the opinion of the author, locomotive designers should study the problem of increasing the capacity and efficiency of present day locomotives. This should be done without adding much to their present size.

The design of driving boxes and driving box brasses has not successfully kept pace with the rapid increase in piston thrust. In the authors opinion we shall continue to have trouble in taking care of such brasses until a suitable design is produced—one in which the brass will cover much more of the front and back projected area of the journal than is now the case.

* Mechanical Engineer, Lima Locomotive Works. Abstract of paper presented before American Society of Mechanical Engineers at Chicago.

that their dependability for heavy power is no longer in question. Many men are studying this particular feature of locomotive design and operation, and we may confidently predict in the future a gradual increase in the efficiency of these mechanisms.

It has been proved without a doubt in foreign countries that the feedwater heater is an essential capacity-increasing device as well as an economical addiapaprently do not 3—chrld and thooob tion to the locomotive. In Germany they apparently do not now consider producing large locomotives without this device. In this respect, then, it would seem that we are somewhat behind the Euopeans, and there is no doubt that in the near future when the economies that can be effected by its use are realized it will become almost as general as the superheater to-day.

Another small item which has received only passing attention in this country is the variable exhaust. As is well known, a variable exhaust that can be properly operated and which will not require much maintenance attention will have a great tendency to relieve high back pressure at high speeds, and its operation will also provide the necessary draft at slow speeds. European locomotives in a great many cases are equipped with such a device which sems to give satisfaction.

The Engine Proper

There have been no radical changes in the general design of cylinders. The use of outside steampipes has resulted in advantages both from a casting and maintenance standpoint. It would seem well worth while to consider a design of cylinder by means of which the weight could be reduced to a great extent, permitting of additional weight of other parts and thereby increasing the capacity of the locomotive.

The design of valve gears has received a great amount of attention and many accepted types are now available. In all of these every effort has been to better the steam distribution. In maintenance we are far ahead of engines used twenty years ago. There is yet, however, much to be desired in steam distribution, and this subject will bear as careful study in the future as it has in the past.

Power Transmission

When we consider that as much as 150,000lb. piston thrust is being transferred through a single main rod and from this into the driving wheels of a locomotive, it is not difficult to understand why troubles are experienced with main crankpins and particularly siderod bearings at the main pin. In order to provide the proper strength to take care of this tremendous thrust it has been necessary to design extremely heavy main and side rods. Further the inertia forces, particularly in drifting, at times reach figures that are even greater than the piston thrust. Practically all of this must be taken care of through the main crankpin and the necessary connections to the side rods at this point.

All are familiar with the efforts made to produce a steel that would give a higher elastic limit than the ordinary high-carbon open-hearth steel successfully used until engines reached their present proportions. The employment of such steel for side rods, main rods and piston rods has been principally confined to heat-treated and quenched forg-

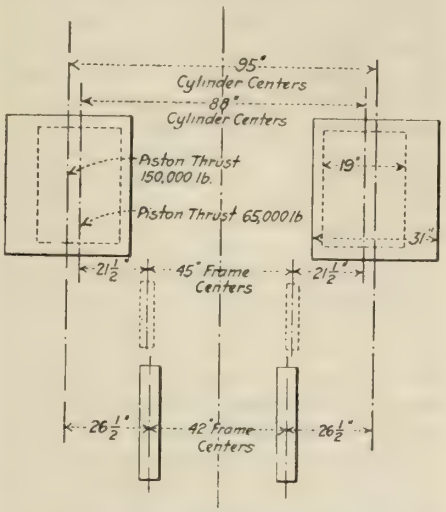


Fig. 1.—Diagram showing increase of overhang of cylinders in present-day locomotives.

ings, which are considerably lighter in section than when the ordinary open-hearth annealed forgings were used. Steel has also been produced which gives a high elastic limit and which can be successfully used with ordinary annealing. The use of such a steel does away with quenched forgings and permits of rods being heated for closing in straps and similar work without destroying the quality of the material as is the case with quenched forgings.

Main and side rods have been produced and have been in successful operation for the past few years in which the piston thrust is carried directly from the main rods to the side rods back of the main wheel. This does not in any way reduce the piston thrust that must necessarily come on the main rods. At the same time, however, it does reduce very considerably the piston thrust that must be transferred through the main crankpin into the side rods, thereby alleviating to a very great extent the troubles that have been experienced with large side-rod connections at the main pin. Such a design does not increase the total weight of the rods to an extent likely to cause any appreciable increase in difficulties from a counterbalance standpoint.

It is impossible to take into account all the stresses produced in rods when a locomotive is in operation, and for this reason the allowable fibre stresses in tension, compression and bending must be small in comparison with the elastic limit ordinarily obtained in such forgings.

Rod design is a study in itself and presents a subject the details of which cannot be covered in a paper of this nature. Hollowbored piston rods, light designs of crosshead and piston, the use of high-tension steel for side and main rods, as well as the use of hollow-bored crankpins, are familiar to all. More careful attention should be paid to the quality and upkeep of rod bearings, and every endeavor should be made to provide bearings of such quality and design that renewals will be reduced to a minimum.

Before the advent of our present-day large locomotives with their tremendous piston thrust it was not a particularly difficult matter to design a suitable main crankpin. In order for it to be of sufficient size to withstand heavier piston thrust and still maintain the fibre stress within workable limits, it was found necessary to increase the diameter proportionately. This brought up the question of rubbing speed. It is a well-known fact that if the rubbing speed is too high, bearings will heat and wear very rapidly regardless of the bearing pressure. A main pin designed properly for heavy piston thrust must therefore be so proportioned that the length will bear a certain relation to the diameter within very close limits. On account of the necessity for keeping cylinder centres as close together as possible because of road clearances, if a proper length of main pin is obtained, its proper size presents a difficult proposition. This is one of the great difficulties which the author is confident will be overcome in the future by the proper application of a design previously mentioned, wherein a large part of the piston thrust is transmitted directly from the main rod into the side rod, thus reducing the force that previously has been taken through the comparatively short and large diameter main side pin.

Counterbalance.

There is a great diversity of opinion in regard to the proper amount of counterbalance which should be applied to locomotives. We ordinarily think of a locomotive being counterbalanced properly when it will ride satisfactorily and without excessive vibration, and it seems that this is the rule by which counterbalance is judged.. There are in operation heavy Santa Fe type locomotives which have between 35 and 40 per cent. of the reciprocating weights counterbalanced, and they are said by traveling engineers to ride easy. The author believes that with our present heavy engines with long wheelbase it is not necessary to balance as much as 50 or 55 per cent. of the reciprocating weight. In fact, it is quite possible that we may be able to counterbalance a smaller percentage of reciprocating weight than has heretofore been attempted, especially for long, heavy engines, provided the revolving weights at the main pin can be properly taken care of. Every effort, however, should be made to balance all of the revolving weights on the

main pin. If, for example, we lack 400 lb. of balancing the revolving weight on the main pin, the effect on the track is exactly the same as if we had 400 lb. of counterweight on any of the other wheels to balance reciprocating parts.

On account of the extremely heavy weight required at the main pin in order to have the proper strength of parts, particularly for large freight locomotives, it is a difficult matter to balance very much—if any—more than the revolving weights at this point. This being the case, if as much as 50 or 55 per cent. of the reciprocating weights is to be balanced, it is easily seen that all of the counterweight for reciprocating parts must be added to the counterweight in the wheels other than the main. Thus, in order to balance a high percentage of reciprocating weights on engines of this class, it is necessary to add counterweight to the wheels other than the main to such an extent that track stresses and riding of the locomotive at comparatively high speeds become a very serious question.

The author is of the opinion that no definite set rule can be established in this regard, but that each particular design is a study in itself, and wherever revolving weights at the main pin are encountered such that they cannot be properly counterbalanced steps should be taken to provide the best means possible of reducing revolving weights at this point as well as providing reciprocating parts as light as possible consistent with strength. This of course has been accomplished in the past by hollow-boring the main pins and piston rods and by using a light design of piston head, which indicates that a steel having a high elastic limit with the proper elongation and reduction of area should be employed.

The Running Gear

On account of the large increase in the size of cylinders of present-day heavy locomotives over those used several years ago, the cylinder centres have been spread until they have reached practically the clearance limitations of the railroads; and the necessity for larger journals to carry properly the increased axle loads has caused the frame centres to be brought nearer together.

This condition increases very materially the distance from the centre of the cylinder to the centre of the frame, which of itself produces greater strain in the frame and at the same time increased pressures on the driving-box bearings as well as on shoes and wedges. In addition to the above, piston thrusts have increased from approximately 65,000 lb. to approximately 150,000 lb., and means must be provided to properly take care of the increased piston thrust along with the increased overhang.

Fig. 1, it is believed, shows very clearly the increased forces that a frame must stand in order to properly take care of the tremendous increases in piston thrust as well as the increased leverage caused by the very considerable lengthening of the distance between the cylinder centers and the frame centers.

Substantial and sufficient cross-braces should be applied between the frames and rigidly bolted thereto to form a rugged structure which will not rattle to pieces. Sufficient bearing for bolts and adequate bolting flanges are a very important feature. At the same time it must be borne in mind that there is a possibility of tying up the frame so rigidly that there will be a tendency for failures ahead of the front pedestal and just back of the cylinder to fit at a point where it is practically impossible to obtain sufficient reinforcement.

It seems as though the design of driving boxes and driving-box brasses had not successfully kept pace with the rapid increase in piston thrust. It is very evident that we shall have trouble in taking care of driving-box brasses until a suitable design is produced—one in which the brass will cover much more of the front and back projected area of the journal than is now the case. Many experiments have been tried, and in many cases they have gone beyond the experimental stage and have proved to be very satisfactory. Among these are driving-box brasses cast into the driving box. Many boxes are in use to-day where the brasses are keyed into the box, making them readily removable for replacement. However, the author feels that none of these has approached a solution to the problem which lies in producing a design that will surround the journal with a bearing as completely as possible and still lend itself to comparatively easy maintenance and reasonable cost.

Guiding and Trailing Trucks in Connection with Long Wheelbase

Santa Fe type engines with 22-ft. rigid wheelbase are not uncommon. Engines of this type and of this size will weigh in the neighborhood of 400,000 to 420,000 lb. When we stop to think that to move this tremendous mass of material around a 16 or 18-deg. curve a force of many thousands of pounds is required, is it any wonder that we obtain rapid flange wear and the necessity for returning tires before the proper amount of mileage has been obtained? In the majority of cases, it is believed, the force necessary to properly curve an engine of this kind has been applied at the front truck and the first driver. In most cases types of leading trucks have been used which produce a very small resistance on curves of small degree. In order to prevent rapid flange wear as well as to overcome the development of lateral play unnecessarily, designs have been produced which will give a high initial resistance of the front truck and provide a lateral motion for the front driver with adequate resistance so that some of the guiding force is transferred back to the second pair of drivers.

Since locomotives operate the greater part of the time on tangent track, it is necessary to have a high initial guiding resistance which will not be increased when curving. In other words, a flexible wheelbase is produced which has all the requisites of the ordinary rigid wheelbase, but at the same time will overcome many of the difficulties now encountered in an attempt to operate engines of this size and length. Many designs of trailing trucks have been produced with the idea in mind of helping to remedy the conditions which have been noted above. These of course have met in a way the conditions which it was necessary to overcome. What is needed is a positive centering device whose resistance will be adequate initially, can be always depended upon, and which will not mount up to prohibitive figures under the maximum swing of the trailing truck.

In addition to the foregoing, some work has been done in the way of producing a design by means of which the lateral play in locomotive driving wheels can be taken up without removing the wheels from under the engine or taking the boxes off from the axles.

The advent some years ago of the power reverse gear overcame one of the great objections that engineers had to large locomotives. It is a fact that it is almost impossible for one man to reverse one of our large locomotives equipped with the ordinary hand reverse lever. Power reverse has come to be an essential part of engine equipment and has been found to be economical even though it may be used on a locomotive which could be comparatively easily reversed by hand.

Probably no one thing contributes more to the failure of side rods than the improper adjustment of shoes and wedges. If these are allowed to run loose, stresses in the side rods will amount to a very high figure, and if they are improperly set up, the driving wheels are very likely to be out of true This in itself brings undue stresses on the rods, which in time will unquestionably produce failures. The author feels that there are many cases where in attempting to overcome the failure of side rods we have deliberately increased their sections without giving due consideration to the cause of failure. Consideration of the foregoing brings us to the point of providing an adequate automatic adjustment of the wedge so that the difficulties mentioned will not be encountered.

Means for Increasing Nominal Tractive Power

All railroads have points on certain divisions where there is a critical grade or the necessity of starting a heavy load under adverse conditions. At such places increased tractive power is required which is not needed elsewhere. We are therefore confronted with the problem of producing a device which can be set to work to increase the tractive power of a locomotive in such cases, thus enabling the engine to take its full tonnage over the entire division. This device should be so made that it can be applied when necessary and thrown out

when the additional tractive power is not required. Designs have already been produced wherein an additional tractive power of 8,000 or 10,000 lb. has been applied to the trailing trucks of large locomotives. There is also a possibility of applying such a device to the tender truck, thus availing ourselves of the adhesive weight of the tender to help boost the engine over the critical points in a division. There is always present a possible potential boiler capacity which can be brought out by the use of a variable exhaust or other device sufficient to obtain rapid combustion at slow speeds.

The Ash Pan

The question of ash pans is also one needing serious consideration. There are in use a number of rules stating what the proper air opening in the ash pan should be, and while many of these rules have in a way proved satisfactory, it would nevertheless seem that to get at the question logically we should determine the amount of coal that can be burned economically per square foot of grate and then on this basis provide an ash-pan air opening that will give the required amount of air to burn satisfactorily the maximum amount of coal which is expected to be consumed. The amount of air that will flow through a given opening in the ash pan, it is believed, can be very closely approximated from the vacuum produced in the smokebox. This of course is only a suggestion, and it may be that when the question is looked into more carefully a more desirable and accurate method of determining the required ash-pan air opening may present itself.

Lubrication

With our present high superheat the proper introduction of oil into the cylinders and valves of a locomotive is worth serious consideration. In many cases oil has been provided to both the cylinder barrel and the steam chest of superheater locomotive, and in other cases it has been provided to the steam chest alone. Both methods have given apparent satisfaction, but it is a difficult matter to state which is the better. It is common practice in European countries to provide a forcefeed lubricator located very close to the cylinder, with a pipe to each end of the piston-valve steam chest. This oil supply opens directly over each end of the valve when it is in central position. In addition an oil pipe is supplied to the cylinder at its center. It is reported that by this method there is less carbonization of the oil than when it is fed into the steam pipes or into the center of the piston-valve steam chest.

In order to increase the tonnage which a locomotive can haul it is just as vital to decrease the resistance as to increase the power. Now it is not an impossibility to provide roller bearings for passenger cars, and there seems to be no reason why they cannot be used on freight cars. The reduction of rolling resistance and the better facilities for lubrication which would be provided would be sufficient in time to overcome the necessary expense.

This question of lubrication may as well apply to other parts of the locomotive. The proper grooving of side-rod and main-rod brasses, or the use of babbitt inserts are questions that should be taken up in connection with lubrication of these parts.

In summing up the situation, it may be said that the use of the superheater alone has increased the capacity of locomotives when compared with saturated engines of the same design to such an extent that no one would think of building a large locomotive for up-to-date railroad service without the application of superheat. We must not content ourselves, however, with what has been done with this one device. What we need to do now is to avail ourselves of the opportunities offered in the application of many of the labor-saving and capacity-increasing devices which have already been worked out and are giving satisfactory service, and at the same time look forward to the possibilities of applying other devices which are yet in their infancy, but which have proved without doubt that they are well worth our consideration and are of sufficient importance to warrant their adoption. Without the capacity-increasing devices which have been mentioned the large locomotive of today would be impossible. It could not be operated satisfactorily. Our large engines are an absolute justification of these improvements. Further developments are ready at hand and in their use lie the possibilities of still more powerful and economical transportation units built to operate within our present limitations of clearance and permissible rail loads.

CONDENSED LAP JOINT TABLE

In selecting the best joints for water tanks, the question often arises whether it is more economical to use the thinnest possible plate with as many rows of rivets as possible, or a thicker plate with fewer rivets. With the net section required for any joint as a known quantity, the question of the proper combination for plate thickness and rivet size is somewhat of a problem. Most lap joint tables are of little assistance in helping you to settle the question, as a number of selections are usually possible.

Recently "Water Tower" presented the table shown, and as it is unusually concise we reproduce it for our readers benefit. Speaking on the subject the writer says that the user has no choice whatever but to take the joint giving the required strength. In the table, however, they have taken the ordinary complete lap joint table and eliminated the undesirable combinations, leaving only what they believe are the most economical joints for water tank work. The plates vary in thickness from ¼ inch to ½ inch by sixteenths of an inch. Plates thinner than ¼ inch should not be used for water tanks on account of corrosion. Plates thicker than ½ inch should be joined with butt straps on account of greater economy. No thirty-second inch thicknesses are given as these are usually odd weights, not kept in stock, and in normal times more difficult to obtain.

Furthermore, the pitch is not based on the extreme maximum efficiency obtainable, but is a number divisible into 69 inches, this being the distance between gauge lines of a 72-inch plate. A 72-inch plate is selected because it is one of the most common widths and a size usually kept in stock by tank manufacturers. In calculating the joint, the pitch giving the highest efficiency was first found and this modified slightly to conform to the above conditions. The true efficiency and net section were then calculated and in all cases are but slightly under the maximum. This gives a joint which more nearly agrees with actual working conditions than a joint based on the highest possible efficiency.

The usual assumptions are used in calculating the table; namely, the ratios of the values of the steel in tension, shear and bearing are as 1, ¾ and 1.5, and ⅛ inch was added to the diameter of the hole to allow for damage to the plate in punching.

LAP JOINTS FOR WATER TANKS

PLATE THICKNESS	RIVET DIAMETER	NUMBER OF ROWS	PITCH IN INCHES	EFFICIENCY %	NET SECTION SQ INCHES PER INCH

		4	3.83	77.1	.337
1/2"	3/4"	4	3.45	74.6	.373

The United States census bureau have issued figures showing the number of establishments and value of output of smelting and refining plants in the copper, lead, and zinc industries. In the copper industry there were 33 establishments in 1919, compared with 37 in 1914. The output in short tons (2,000lb.) at smelters and refineries respectively in 1919 amounted to 655,486 tons and 931,790 tons, compared with 575,069 tons and 782,854 tons in 1914. The works engaged in the lead industry in 1919 numbered 25, against 22 in 1914, while the output of smelted material amounted to 485,612 tons and 563,810 tons respectively. Zinc works numbered 38 in 1919 and 29 in 1914, while the output of smelted product amounted to 465,743 tons and 353,049 tons respectively.

Welding of a Caulking Edge on a Boiler or Tank

It Pays to Know More Than the Regular Routine of Work—Putting Refractory Plates and Angles in Place—Building Up a Broken End of a Shaft

THE welder who knows only the regular tasks, never goes far. He may hit up against some difficulty, and it is then that his resourcefulness is under test. The matter to follow illustrates and explains some interesting and useful welding dodges, so that those interested in this branch of the business should read each hint carefully, remembering them for future occasions.

For example, Fig. A shows a method of making a lapped plate joint where the edges do not come together flat or the plate bulges between the means provided to hold them together, such as a few bolt holes spaced some distance apart. Another use for this scheme is getting refractory plates and angles in place in ship barge work and perhaps later this scheme will be used in large size ships. The idea is simply to tack a bolt by its head upside down on the lower or inner plate, tacking it by single fillet across two edges only. The heavier plate used as a clamp is then brought down with a nut to bring the upper or outer warped plate into place. After this plate is tacked down and nut can be removed and the bolt knocked off at right angles to the weld or if this proves troublesome, one of the welded beads can be chipped off and then the bolt head can be knocked loose pushing from that direction. This method should be acknowledged to Mr. W. T. Bonner, who devised it and first used it in ship work.

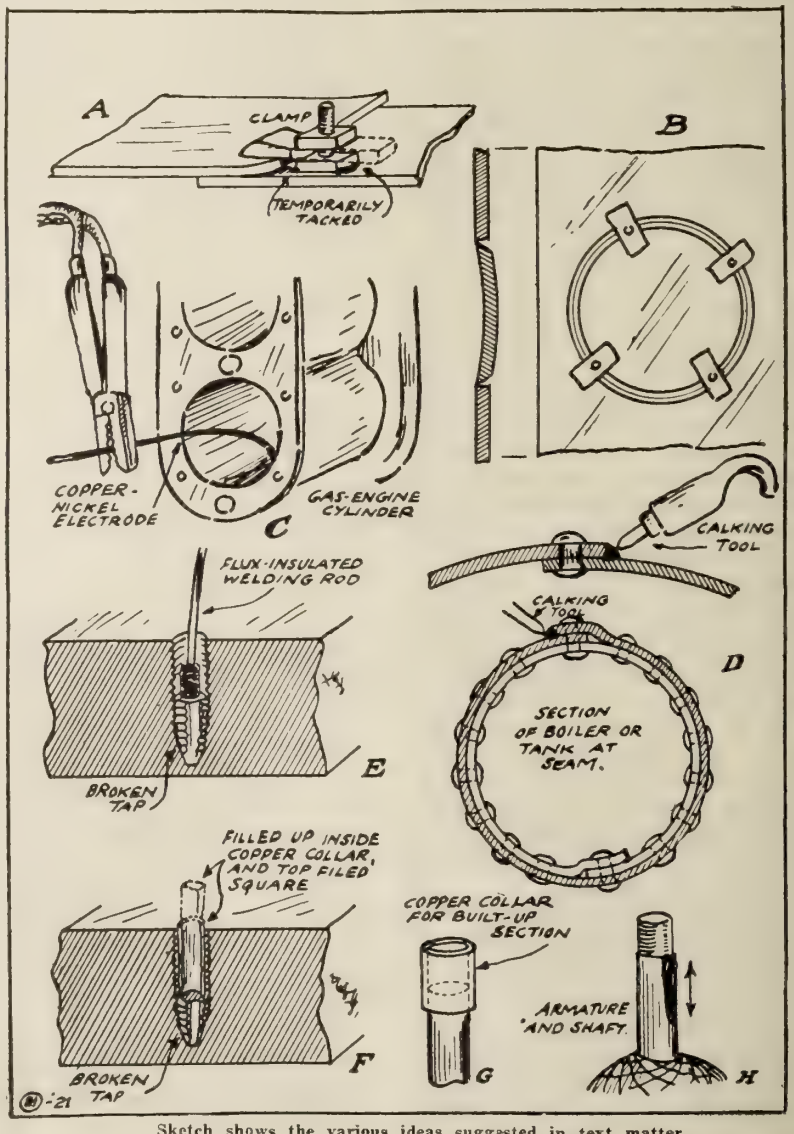

Illustration B shows a method of putting in a patch in a plate whether a plane, round or warped surface where much trouble has been experienced in keeping a welded patch from cracking during the welding or after welding or in service or where from experience such danger is liable. In the cross section you will note the patch is slightly dished, the idea being that the contraction during welding will just about take up the dishing and straighten out the plate that is used as a patch relieving all strains. The ideal patch in this case is a circular one but oft times a true circle cannot be arranged for but the nearer a circle is approached the better the chances are for success. For instance, if the hole is rectangular, rounding the edges will help a whole lot and if the hole is odd shaped, making it an ellipse or egg shape will approximate the circle where the stresses are even all around.

Where a machine formed dished patch cannot be obtained an ordinary sheet can be dished by hammering. If the sheet is over ¼ inch thick it should be hammered hot and it is best hammered hot for any thickness.

The four clamps show an easy method of holding the plate in place, simply putting a bolt through from the inside and clamping down with a heavy plate and nut on the outside. These clamps should be left in place as long as possible in this rigid system of welding. This system not being at all applicable to the non-rigid system as it is a rigid weld with the stress tranferred to the dished patch.

Fig. D shows an apparently easy job to the initiated, that is the welding of a caulking edge on a boiler or tank. This job is far from being easy, because in most cases the welder is called to fix up a leaky seam and the cause of a leaky seam is movement of the plates or rivets. Simply running a caulking edge along the joint will in general make the seam tight when not in use, but upon the boiler tank being put in service, especially under pressure, the plates are liable to assume a different shape or position under load than when quiet, the strain then being entirely brought upon the weld whereat it is broken or pulled away, adequate provision not having been provided to equal the strength of the plates to which it is welded.

It is not always the correct thing to do to make this weld stronger than the plate. In a boiler, for instance, where rivets have been installed for part of the seam, it is best to fire up the boiler and put it under full pressure, thus straining it into its final position before welding. Illustration D shows how a caulking seam should be approached with the tool so as not to drive the weld under the plate. A great deal of experience is needed in caulking for arc welding just as caulking experience is

Sketch shows the various ideas suggested in text matter.

Extracted from a handbook published by the Electric Arc Cutting & Welding Co., Newark, and reproduced through the courtesy of said company.

maker knows that an amateur will do needed for rivet work. Every boiler with a caulking tool more harm than good and similarly in welding; too much caulking is harmful instead of beneficial. A multiplicity of light rapid blows is the only reliable caulking method on a weld, whether the caulking is for a smooth finish or to make the surface denser against weeping. Also, too much caulking will cause the surface of the weld to crumble and repeated caulking of this nature will finally result in crumbling the welding all away.

Caulking rough looking welds for a finish is common practice, but in this case the rougher part of the weld must be chipped or ground approximately the size before caulking, or the efficiency of the weld will be much lowered, both as to strength and tightness. Working a weld cold except on the surface would be similar to working a sheet cold of similar dimensions which could be easily cracked or ruined. Working the weld hot is a different matter, but it is almost impossible to caulk metal arc welding while hot, although in many instances on very careful work each inch or two is caulked while hot (just after it is put down) with a ball peen hammer in the hands of the welder. In very few instances the weld can be reheated and caulked but these are very scarce as reheating would in general cause more strain and stresses than would be relieved by caulking.

Filling In Scored Cylinders

Illustration C shows the proper method of filling-in scored cylinders with the latest development, the copper nickel electrode, which has the property of so merging with cast iron that the usual hard spot underneath the weld is done away with. This copper nickel electrode is far better than the old pure nickel peened in, as the copper nickel can be welded in continuously; care being taken not to get the cylinder wall too hot, that is weld not over two or three inches at a time. The excess metal can be machined off with any common ordinary tool or a lathe or boring mill or can be ground nearly to size and can then be rolled and lapped afterwards.

The illustration shows the electrode bent so that the tip is approximately at right angles to the score to be filled. This is a repetition of previous instructions on this point, i.e. that no arc weld can be made properly unless the electrode tip is very nearly at right angles to the work piece surface. For this copper-nickel electrode even although the score is very small at least ⅛ inch size electrode must be used, as 130 amperes is about the smallest good value that will reliably weld the cast iron and a ⅛ inch electrode is the smallest that will carry this current. For larger work a 5/32 inch electrode is best.

Fig. E. and F. show two methods of reclaiming broken taps in thick pieces or castings which method is not new by any means. There is nothing more exasperating than to break a tap, especially a bottoming tap below the surface of the main piece. The tap must be gotten out or the work is ruined. If the hole is large an insulated rod can be used to build up on the tap until it is above the surface where a square can be filed on it and tap backed out. The insulation on the rod helps to prevent spoiling of the thread by accidental contact. The method here is to weld a bit at a time or if you have become expert at dipping in and out of the puddle, the building-up can be made practically continuously by shorting the arc in the puddle and pulling away to a very short arc before the puddle freezes, This method is also very useful in building-up oft-times at other places than in a hole.

Where the hole is small an extra tube shoved down inside the threads will allow of the added metal being built-up to the surface in order to file a wrench grip to back out the tap. Illustration G shows a method of building up a broken or chewed off end of a shaft where the end is not more than 4 inches to 6 inches long. The copper collar is here banded on the inside, the collar being not more than 1½ or 2 inches higher than the welding surface at any time, being pushed up successfully as the bilding up progresses. This method is far better for short pieces than trying to weld on a piece as it does away with the necessity of veeing out, aligning, etc.

After the weld is made the copper collar should be removed and a finish made for subsequent machining by welding lengthwise of the shaft, similarly as is shown on the armature shaft, illustration H. These welds should always be made lengthwise of the shaft in order to ensure an even deposit because in welding around the other way the welding setting is only right for one position and is too hot for the vertical welding and not hot enough for the horizontal. This welding of armature and other shafts, by the way, where the bearing is worn or scored or the keyway is chewed out, is one of the most useful applications of arc welding, as there is practically no danger of putting heat enough into the shaft to melt adjacent babbitt or ruin adjacent windings.

The illustrations on the sheet and angle work show some special applications of joining two or three or even more of the regular structural members for structural work. When joining two plates at an angle, if the sheets are left a bit spread the pieces can be joined reliably in the one weld. The wider the plates are apart, the more reliable will be the joining of the inner three pieces and at no time should the plates be apart a smaller distance than their thickness. The illustration to the right of this shows a method of stiffening a sheet either for attaching to an upright or not.

The angle bending and welding method shown in the center top is one of the most widely used applications of arc welding but is shown as an idea to extend the arc as arc welding is only started. You will note that any angle can be allowed for by cutting out the V to correspond. The illustration to the left of this shows a method of joining by a combination of arc welding and bolts, members which must be removable. The window frame method itself is self explanatory, it being found much easier to chamfer off the window slightly than to make a flush weld and perhaps ending by having to chip the weld. The corner sheet method is similar to the joining of the three pieces explained at the start of this section. A weld made in this manner and finished off a bit is the prettiest joint yet devised.

Where an angle would be objectionable or the plates are small the weld can be butted on the outside at right angles and not welded at all or just welded for finish only.

Unique Method of Welding

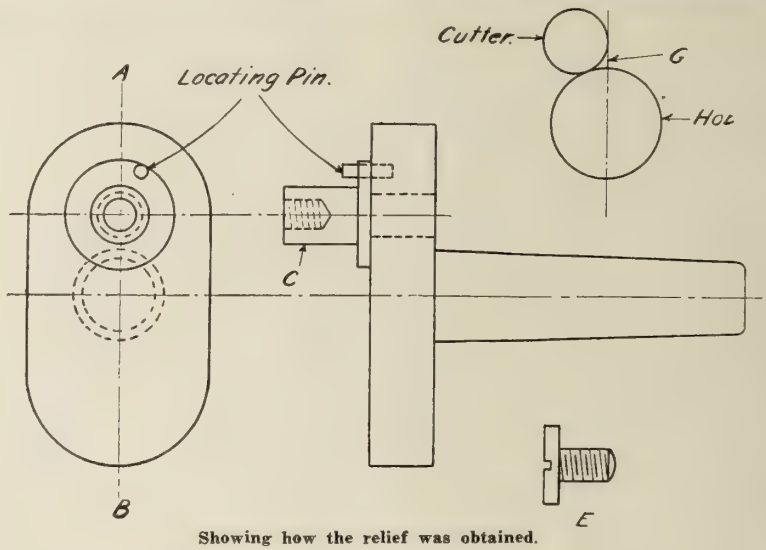
A unique method of welding is shown left of this where a lapped joint must be made for a third member and the three of them joined. The illustration shows how one of the plates is nicked out and the other one laid over the notch half way the width of the notch so that the weld can be made through this opening to the third member, at the same time joining the two sheets. The sketch of the veed out plates is shown for several reasons, one that the angle of the "V" must vary with the thickness of the plate for an even flush butt weld, being thicker for heavy plates. In general, however, a right angle opening is the maximum required.

Welding long seams butted brings up the question of the rigid or non-rigid method. In the rigid method the plates are clamped or bolted in their final alignment and the weld made in any manner, either continuously or broken up to spread the resulting contacting stresses over more time and plate. In the non-rigid system the plate is placed close together at one end and the part at the other end and the weld made continuously closing in the opening at an even rate which will just bring the closed ends together at the finish of the weld. This method requires more skill and experience than the non-rigid and in any ordinary job is not worth the trouble it entails, although for very careful work it may be desirable to use it where joining two pieces only.

It is evidently more out of place in setting in a patch as the only part of the patch on which this method can be used would be the first seam. There is a use for it, however, even in setting in patches in some very rare cases where the difference between success and failure depends on getting the first edge of the seam perfect so that it will not be pulled away due to the contracting strains when welding the opposite seams or the seams at right angles which exert a more tearing pull than the opposite seams in contracting.

An aid which is hard to obtain but which has been found very useful in very careful work is to vibrate the work while making the weld by light blows of the hammer or vibrating the work directly after the weld is made, i.e., while it is cooling and contracting. The vibrations of an air hammer set for a light blow is the best means for accomplishing this.

WHAT OUR READERS THINK AND DO

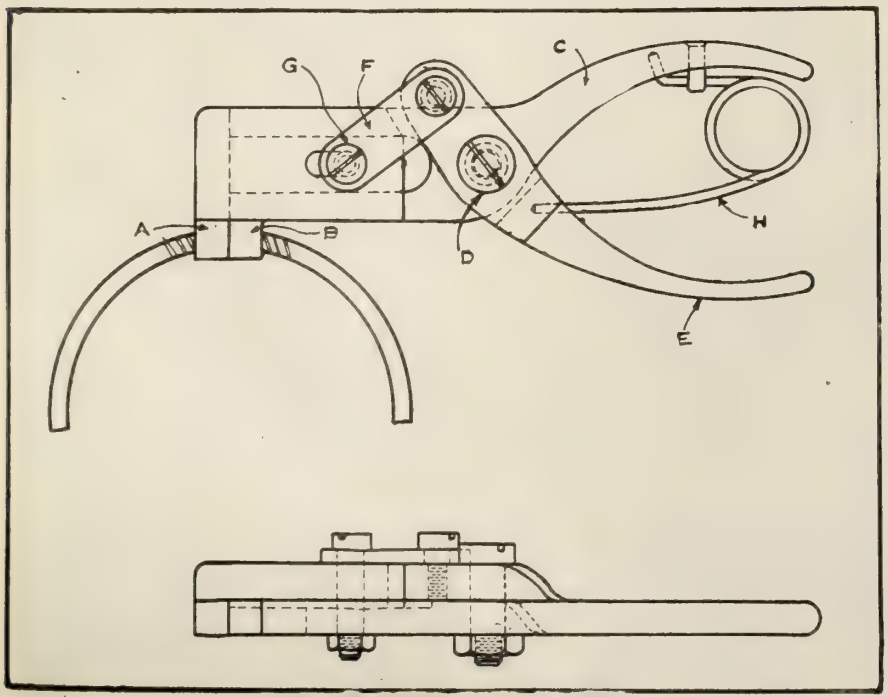


TOGGLE ACTION PLIERS

By F. M.

An unusual construction as applied to pliers is shown by the accompanying illustration inasmuch as the action of squeezing the pliers causes the jaws to open parellel with the pliers in such a way that they hold open the spring tempered ring shown in position.

These pliers consist of a pair of jaws A and B, jaw B is in part an extension of handle and frame C, attached to C by means of a pivot screw. D is a handle E, arranged in such a manner as to form a toggle. Operated by E is a link F. This is attached to jaw A by means of a screw G passing through an elongated slot in the frame portion of jaw B. In addition a spring H holds the operative handles apart, thus it is evident that by merely pushing the handles together, through the medium of link F, the jaws A and B are caused to spread apart to perform the desired function of opening the ring.



Showing how the relief was obtained.

RELIEF ON THREADED HOBS

By G. Russell

The jig shown in the accompanying illustration was recently developed to obtain the necessary relief on threaded hobs of the ring type on the milling machine. The Hobs were fluted in the usual manner having 12 flutes, the index head being placed with the worm screw at right angles to the face of the miller. The jig was placed in the head centre with its centre line A B at right angles to the table. The hobs were placed on stud C. A pin was used for locating, and was placed the distance of one flute off the centre line. The hob was held by screw E and an end mill was next placed in the miller to remove the excessive stock, being set up as illustrated at G. The worm crank was gradually turned by hand until the cutter ran into the next flute. Reversing the worm crank and loosening the clamp screw, the hob was turned one flute repeating the operation until all flutes relieved. Substituting the end mill for a threaded hob the operation was continued in the same manner until completed.

Showing the method of using the pliers.

KILLING "ATMOSPHERICS"

One of the most troublesome difficulties in wireless telegraphy is the interference caused by what are known as "atmospherics." The receiving instruments are affected by electric waves which arise no one quite knows how. They are worse during the day than at night and also during certain weather conditions. For many years a British company has been striving to overcome this difficulty and it has at last been rewarded by the discovery and perfection of a device by which the effect of "atmospherics" can be quite eliminated. What this means in practice is that existing wireless stations can carry far more messages than they have yet been able to do. Every now and again the use of automatic signalling at high speed had to be given up and oral reception employed, owing to the way in which the atmospherics played havoc with the machine records of the signals. A skilful operator could disentangle the human signals from nature's freaks, but the speed at which an operator can receive is limited. It is not too much to say that this invention will multiply the efficiency of wireless telegraphy ten-fold.

The Benefit Of Copper

AFTER conducting a series of tests to determine the relative loss of metal in tie plates of various compositions, including those containing a small percentage of copper, the New York Central lines have arrived at the conclusion that tie plates rust less when a certain percentage of copper is existent.

The length of time over which these tests were conducted varied from two years to a maximum of six years, and in fact some of the tests are still in progress. In all cases the maximum corrosion developed on the bottom or under side of the plates, contrary to the generally accepted theory of most engineers and maintenance of way men that the maximum corrosion takes place on the top or exposed portion. The percentage of copper in the plates containing that metal ranged between 0.25 per cent. as a minimum and 0.5 per cent. as a maximum, the plates so treated being rolled otherwise, according to the standards of the New York Central. The copper-treated plates so obtained were subjected to the same tests as the other plates. An exposed test on a number of steel tie plates rolled from mild Bessemer steel containing 0.25 per cent. copper and a number rolled according to the same specifications without the copper content showed an average loss of 8.88 per cent. for untreated plates and only 1.46 per cent. for the treated plates.

A second exposed test was made which covered a larger number of tie plates rolled from metals of various compositions. The plates used in this instance were cleaned and then exposed on the roof of a building at Hoboken, N.J., where the action of the salt air of New York Bay could be studied. Tests showed loss on the copper plates from 0.46 to 0.72 per cent, averaging 0.56 per cent.

In comparing the data so obtained the nearest approach to the results reported from the copper-treated plates was a loss of 0.59 per cent. for high carbon open-hearth steel, too hard to punch. The pure iron plate came next, with 1.17 per cent., and then the high-carbon Bessemer plate, with 1.77 per cent., the latter also being too hard to punch. The remainder, which were standard steel tie plates, varied from 4.70 to 6.60 per cent., showing for common or regularly accepted tie plates 8 to 10 times the loss for the special copper-treated ones.

Systematic Disposal Of Waste

THERE IS more than one method of selling waste material. Speaking on a recent policy adopted by the Crompton & Knowles Loom Works, on the other side of the line, "Iron Age" says that in the above factory a department has been created especially for the economical disposal of waste.

The principal items disposed of are wood, cold drawn steel, hot rolled steel and iron, tool steel, pipe and miscellaneous items such as glass rods, solder and so forth. The chairman of the committee is a member of the purchasing department, who is in a position to determine the relative values of articles recommended to be manufactured from scrap materials.

The committee meets the first of each month and the chairman calls on each member separately concerning scrap produced during the previous month for which he is responsible. A report is then submitted as to the quality of scrap on hand according to classification. This material is properly cared for in the stockroom, where men in charge are familiar with department raw material requirements. The labor charge of working up salvaged material actually is larger than it would be otherwise, but not sufficiently so to more than offset the savings in raw material cost. Workmen much prefer not to handle salvaged material; consequently, there is a tendency to eliminate it as much as possible.

In the company's foundries a Make-Every-Ton-Count committee is incorporated to work in conjunction with the main plant reclamation committee. Ways of disposing of scrap materials are varied. It is not always possible to net the company a profit, especially on falling markets, but instances cited illustrate the resorcefulness of committee members in the early part of last year.

Saving Worn Machinery

A BRITISH engineer has developed a method of depositing nickel on the worn parts of machinery. This, of course, means the saving of many machines which would otherwise be useless. It is already well known that welding has been used to build up engine crank shafts after they have reached a worn condition, the process being to weld fresh iron or steel on to the worn parts, and the whole then made true in a lathe. There are objections to this process in certain cases, and in order to overcome these objections, the new process has been evolved. Following is the method employed: The piece of machinery to be treated is first made free from grease and dipped bodily in a bath of molten wax. After the wax has cooled it is removed from the parts which have to be restored and is left on the others as a protective covering. Cleaning in a bath of acid is followed by immersion in an electro-plating bath which deposits nickel on the exposed surfaces. The coating of nickel is extremely hard, and when the process is properly carried out the nickel adheres with remarkable tenacity to the metal on which it has been deposited. Crank shafts, spindles, axles, pistons and similar objects can be made quite serviceable again by the nickel layer at a cost below that of replacing the whole part. Deposits up to one-eighth of an inch can be applied successfully. It is expected that this process will be developed alongside the welding processes which have been brought to so high a pitch of usefulness in many repairs, such as the mending of cracked or broken castings, which could not be handled by the deposition of nickel.

Proofing Fabrics

FABRICS may be proofed against soiling or staining by applying a solution of cellulose nitrate or acetate to the surface. The penetration of the solution into the fabric is prevented by impregnating it with some such volatile liquid as benzine before applying the cellulose solution.

A patent has been granted on a process of using insoluble alginates formed on fabrics by padding them with a soluble alginate and then passing them through a bath of zinc sulphate or similar heavy metal salt, and, according to "Scientific American," the alginate separates in a collodial form, giving a water proof finish which is said to resist a boiling neutral dye bath. Balloon fabrics are rendered more impermeable to gases by the use of a mixture of rubber and cellulose acetate. This is applied in the form of a collodial mixture in such solvents as tetrachlorethane.

Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

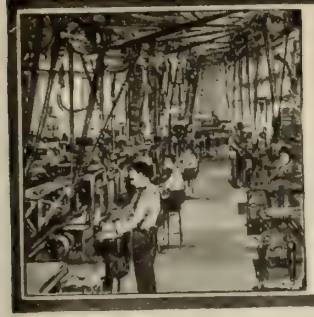
The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

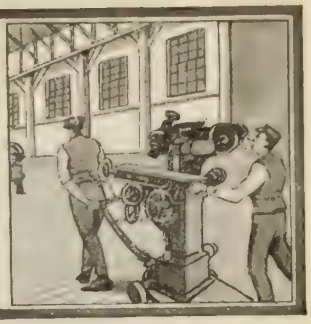
Unfortunately, every reader had a different idea as to the correct solution of the questions in the Sept. 1st issue. Question No. 6 seemed to be the one that fooled the greatest number as only two readers had this particular question correct. No one however, submitted a complete correct list, so that we will award two scales for the contest next week.

CONTEST FOR SEPT. 22ND ISSUE



Contestants are required to write us, stating to which advertisements we refer in this number.

1.—How to get tanked up in spite of prohibition.
2 A case where preference is weighty testimony.
3- How to double the outdoor working hours.
4—A product produced at the rate of 3.333 per minute.
5—Something that pays in the long run.
6—A short life as a bad investment.
7—One of the secrets of efficiency.
8 Something that cries aloud for attention.
9 A good investment.
10 Something that does not depend on bulk or weight.
11—Small but capable of large work.
12 Something with quick smooth control.



These are Correct Answers for List from September 1st Issue

1—Flexible Steel Lacing Co.
2—Fellows Gear Shaper Co.
3—The Burke Machine Tool Co.
4—The Warner & Swasey Co.
5—The Carlyle Johnson Machine Co.
6—The Chas. Parker Co.
7—American Lead Pencil Co.
8—Heald Machine Co.
9—Skinner Bros. Mfg. Co.
10—Landis Machine Co.
11—H. B. Underwood Corp.
12—Vanadium-Alloys Steel Co.

Closing Date for This Contest is September 27th

DEVELOPMENTS IN SHOP EQUIPMENT

SAFETY TOP HOLDER

The Apex Machine Co., Dayton, Ohio, have placed on the market a friction slip tap holder. The principal feature of this device consists of the arrangement which permits of slippage within the holder itself, in case the tap becomes wedged or strikes the bottom of the hole. It is said to be particularly adaptable to use on multiple-spindle drilling and tapping machines. Because of the small outside diameter of the device, use on multiple-spindle machines is quite easy. The tap holder will operate in any position, whether horizontal, vertical or inverted. These holders are made in two sizes. Type A has a body 1¼ in. in diameter and 3 in. long, and will tap all sizes of holes up to and including ½ in. Type B has a body 1¾ in. in dia- [illegible] will tap holes [illegible] the collet the tap is driven by the square and held in position by means of two dogs mounted in a slot at the end of the collet, with the ends protruding into the flutes of the tap. The collet may be inserted or removed by raising the sleeve.

A very large amount of friction surface is said to be provided in the holder, by the use of a number of alternate steel and fibre washers, thus making it easy to maintain the adjustment of the holder. The amount of friction may be quickly adjusted when changing from one size of tap to another. The holder embodies a 3-16 in. vertical float movement, to allow for a slight variation in the lead of the tap. There is also a lateral float of 1-32 inch.

TOOL BITS

The New England Tool and Machine Co., Springfield, Mass., has placed on the market a line of tool bits which are manufactured under a patented process. They are made to fit standard tool holders taking square stock in the following sizes:—3 16 in., ¼ in., 5/16 in., ⅜ in., 7/16 in. and ½ in. These tools are cut from annealed bars. The thread tools are ground on a special block and the flat and angles on the U. S. standard threads are ground with the same operation, proper clearance being allowed. They have a cutting edge on both ends and are offered to the machine shop trade with a view to cutting down production costs by eliminating time spent by workers in grinding tools. Their size permits checking in and out of tool cribs as are drills and other tools, thereby eliminating loss sustained in tool bits as usually handled in the shop.

ROTARY SERVICE GRINDING MACHINE

The Pratt & Whitney Co. Hartford, Conn., have placed on the market a rotary-table surface grinding machine which is equipped with an 8 inch wheel. This machine is intended primarily for the grinding of disks, rings and cylinders requiring flat and parallel surfaces and the maker claims that the sturdy, compact construction permits of heavy [illegible] are provided for grinding concave or convex surfaces.

The spindle is mounted on ball bearings, which are protected from dirt and provided with adjustments for wear. The wheel is cemented in a holder screwed to the spindle, to facilitate changing, and a band clamped around the wheel guards against breakage. Surrounding the wheel is an adjustable steel guard which automatically covers the entire wheel when it is raised to the idle position, so that chuck work can be handled safely.

The machine contains several other features and belt drive is regularly furnished, all necessary guards being provided. The main drive shaft and idler pulleys are mounted on ball bearing to take the load. The two-speed gear shaft is mounted on bronze bearings to take the load. The two-speed [illegible] bearings being lubricated by the splash [illegible] ible coupling takes care [illegible] Individual [illegible] ...nished.

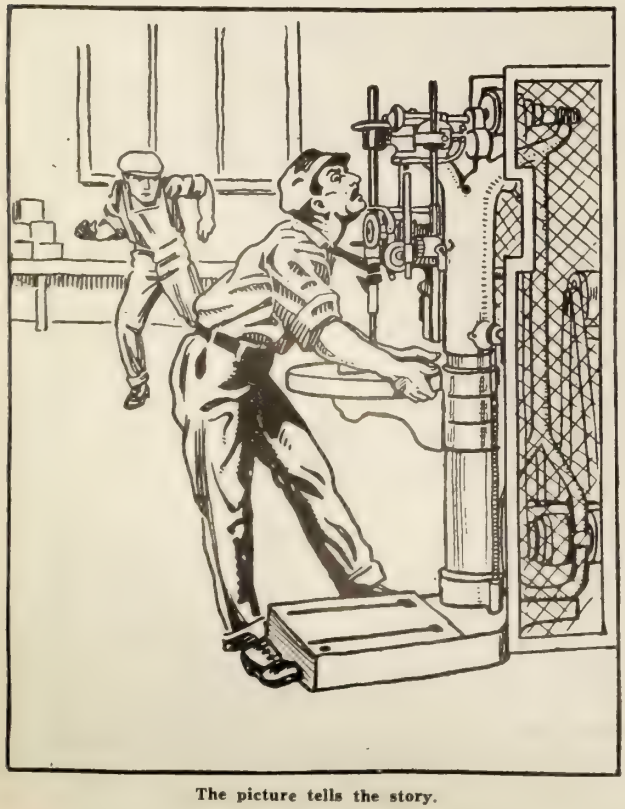
The Value of Suitable Clothing



THE MISSIONARY work being accomplished by the various safety organizations throughout the country cannot be overestimated. There was a time, and not so very long ago, when accidents were considered a sort of necessary evil which, like the poor, would be always with us. The foolishness of this viewpoint has been brought home very forcibly during the past few years, and by means of educative methods, the number of industrial and general accidents has been reduced considerably.

In the early stages of development, workers in industrial plants were rather inclined to view the movement very much in the light of a new fad which would soon die out. The results accomplished soon convinced them that here was a sane movement worth backing to the limit, as it not only suggested, but in some cases enforced the necessary precautions. Efficient guards on machines are now a common sight, rather than an oddity, and it is the machine which is not properly protected which now causes comment. All this has taken time, and there is still much to be done, but the results so far have been reassuring and comforting.

One of the danger points which still exist in some plants is that of improper clothing. Usually a man or woman gives the subject of clothing little thought. They dress neatly, no doubt, but do they put on attire to suit their particular occupation? Take, for example, the illustration shown on the present page. Did the operator of the drill press ever imagine the loose end of his tie would get caught on the drill spindle? Of course not, for otherwise he would have used a neat, serviceable, and inexpensive tie clip to hold all loose ends securely. A little matter, yes, but a very important one.

Lest there be those who are inclined to treat the illustration as an exaggeration, let us quote a case in point. Some years ago, in a certain plant in Hamilton, Ont., an otherwise capable radial drill operator got caught by the shirt sleeves on the spindle of the machine. Before anyone could shut off the power his arm was broken and his back badly injured, owing to the drill swinging him sharply against the large casting he was working with. The shirt manufacturer would no doubt like to get the brand of shirt which held so efficiently, but looking at the thing seriously, what happened? Simply the fact that the operator hadn't rolled his sleeves up CAREFULLY. A small matter again, but think of the result.

No matter how trifling, it pays to be careful. If overalls are being worn, see that no loose flaps are hanging. If the shirt sleeves are rolled up, watch that the rolling is firm and neat. In the case of women, they should avoid waists with frills and loose edges, in fact any portion of their attire should be as simple as possible. Wherever a shaft, belt, or object of any nature is in movement it pays to watch the matter of proper clothing.

The picture tells the story.

* * * * *

Not A New Idea

"HENRY Ford is going to revolutionize railroading." At least that's what one would infer from the various stories which have been printed lately regarding his activities in the railroading game. Looking at the matter more closely, however, what do we discover? Simply that Mr. Ford is going to follow up a practice which is not only in existence, but has proved a decided success.

Anyone who visits Great Britain for the first time might be tempted to laugh at the miniature coaches and cars as used on that side for railroading purposes. The laugh however soon turns to wonder, for the speed and efficiency with which railroads in general in Britain are handled cannot help but call for favorable comment.

There is no question but that light cars save time for both the manufacturer and the railroad. They are easier to handle, take up less yard space, and naturally can be carried along at a better speed, and at less fuel cost. In the case of perishable goods the benefit of speed is all the more evident.

While we cannot expect a sudden change of policy, the time is gradually coming when lighter cars will be in use on many of our railroads. For some purposes the heavier cars will still retain their important position, but for general haulage a car of lighter design will be used. This in turn will mean added life to the rails.

The above comments are not intended to detract attention from Henry Ford's capabilities as a railroad owner, for he has already shown what he can do in this respect. He has taken a losing proposition and turned it into a dividend paying road. In a few years he may have worked similar wonders with his railroads, as he has with his world-wide known car.

MARKET DEVELOPMENTS

Market Situation Shows Further Improvement

Seasonal Activity In Steel Business—Production of Steel Mills Has Increased to 33 Per Cent. Capacity—Machine Tools Are Selling at Fair Rate of Speed—Scrap Market Poor

BUSINESS conditions continue to improve and with the exception of the scrap market, all lines show improvement. Steel production has increased in volume, being now 33 per cent. of capacity. Of course this figure is not an ideal one, but it is much better than the amount shown in the middle of July. The steel men also look for a steady gain from now on.

The machine tool market reports better business. Enquiries continue to come in and in many cases they look like real orders. On top of that this branch of the market has been working on prospects for some considerable time so that some nice sized orders are expected in the near future. Railroads are again beginning to buy, and several orders are reported. This business is expected to attain larger proportions in the near future.

The small tool dealers report a steady demand. While the orders are of the hand to mouth variety there are sufficient of them to make the going worth while. Dealers in this branch of the market are quite satisfied with their position.

The scrap market remains dead. Nobody wants to buy. This applies to consumer and dealer alike, so that one cannot expect a change in this line for some time to come.

The harbor at Montreal is experiencing considerable congestion owing to grain shipments. Elevators long since out of use are being brought into service. The grain freight situation is responsible for the present condition, and in fact so bad is the congestion that several shipments have been diverted to Quebec in order to eae up the Montreal end.

PRICE CHANGES IN SEVERAL LINES GENERAL BUSINESS IS PICKING UP

Special to CANADIAN MACHINERY.

PITTSBURG, September 22.—The latest report is that the Steel Corporation is operating at about 33 per cent. of capacity. Independents seem to be averaging about the same rate, though some are well below that rate and some well above it. If the industry as a whole is not operating at 33 per cent, it is not far below the rate. As production sagged below 20 per cent. at the middle of July there has been a very substantial recovery.

The present rate is, however, a very low one by any long range comparison. The point is that production recently was far below what anyone dreamed could occur. An interesting point about a 33 per cent. rate is that it represents approximately the minimum tonnage thought possible before the war. That is, the idea then was that the poorest demand that could occur would give the mills about a 50 per cent. operation at least, and the actual fact was that in the whole history of the steel industry, prior to the latter part of 1914, after the war had started, operations never went below about 50 per cent. of the capacity existing at the time. As there has been an increase of about 50 per cent in the capacity since 1914, a 33 per cent of capacity since 1914, a 33 per nage as a 50 per cent. operation in 1914, viz., about 17,500,000 gross tons of steel ingots a year, or about 185,000 net tons of finished steel a week.

Price Changes.

The best evidence that prices are nearly if not quite at bottom, as long as wages, freight rates and other fundamental items of cost are at their present levels, is that steel prices are moving both ways now. Our last report recorded an advance in wire products, prices having advanced $2 a net ton on plain wire, $3 a ton on barb wire, 10 cents a keg on cement coated nails and 15 cents on wire nails, the new prices being $2.60 for wire, $2.45 for cement coated nails and $2.90 for wire nails.

Against these advances in wire products may now be set reductions just made in tubular goods. Under the lead of the National Tube Company (Steel Corporation) new discount lists have been issued under date of July 16. Standard steel pipe is reduced, from the list of July 7, 1921, four points on all sizes of butt weld, four points on 9 to 12 inch lap weld and five points on 2 to 8 inch lap weld, the reductions therefore being nominally $8 to $10 a ton. Lap welded steel boiler tubes are reduced five points, while oil country goods are reduced about $10 a ton. The announced reductions in oil country goods are approximately equal to the average amount of shading there has been for a couple of months, while the reductions in pipe are much more than even the extreme shading.

By a similar antithesis, bars, shapes and plates are weaker while sheets are stronger. In bars, shapes and plates it is now relatively easy to place small orders at about $1.65, while attractive orders are reported to have gone at close to $1.50. On the other hand all the independent sheet mills but two or three have advanced their prices $5 a ton, and the American Sheet and Tin Plate Company (Steel Corporation) seems to be on the verge of making the advance. The independents that advanced are now quoting $2.50 on blue annealed, $3.00 on black and $4.00 on galvanized. It appears that they were careful to book all the business they could lay their hands on at the old prices before making their advances.

Wire products and sheets have evidently been too low. Even with a moderately full operation the mills could hardly break even, while with the light operation they have had they show losses. It is true they would have losses if they did not operate, as the overhead would continue, but the mills are apparently concluding that it is unwise and impolitic to allow competition to carry them so far that their losses in operation would be as heavy as their losses from idleness.

Present prices of steel products in ordinary lots, taking wire products at prices before the advance, since the dis-

tributors are covered for about 60 days, are about 28 per cent. above the ten-year pre-war average, 1904 to 1913 inclusive, and about 62 per cent. above the low point of December, 1914, while they are 40 per cent. below the war-control prices of 1918. This means, of course, that there has been a very thorough liquidation, as great a liquidation as can be expected of the mills when they are still paying wages 50 per cent. or more above the wages of 1914 while freight rates are up 75 to 100 per cent. and other fundamental items of cost are much higher than before the war.

General Business.

The fact must be emphasized that steel demand has been having a movement of its own, not in relation to the general business of the country. In the late months of last year and the early months of this year more steel was shipped than was needed for actual consumption, resulting in piling up stocks of steel and of manufactures of steel. These had to be liquidated, and during the process of liquidation the demand upon the steel mills dropped to an unprecedentedly low rate. At the middle of July steel production was at less than 20 per cent. of capacity, but it was not the case that 80 per cent. of the workers in the country were out of employment, or that the freight movement of the country was only one-fifth of normal or that the movement of money through banks was reduced in any such ratio.

The sum total of business in the United States in the past few months has been but little below the volume in 1920 and it is possible even that it has been greater, but there has been a different distribution. House building and road building materials have been moving better than in 1920. The money turnover in stores may be less, but on account of reduced prices the volume of goods handled may even be slightly heavier. The condition is not universally recognized, but it is proved by incontestible statistics.

The condition in steel has been that of a very subnormal demand, in relation to the work the country is actually doing. There is much talk of "unemployment" but there has also been much talk of factories producing more goods with greatly reduced forces, simply because men work now while many in 1920 were drawing wages without doing much work. The number now "unemployed" is said to be nearer 6,000,000 than 5,000,000, but in 1920 the total number of persons receiving wages or salaries was about 45,000,000, and if the remainder were on full time, which is not the case, they would probably, on account of working harder, be doing more work than the whole 45,000,000 were doing last year. With so many men on part time it is possible the total quantity of work being done is somewhat reduced, though that is by no means certain.

Obviously the steel industry is marked for further increase in employment, as stocks are liquidated and normal relations are restored. The tonnage rate of steel production has increased by between one-half and two-thirds in two months, but this does not mean that general business has grown more active by that amount. It means that steel is moving back towards a normal relation to business generally.

POINTS IN WEEK'S MARKETING NOTES

The Steel Corporation is now said to be operating at about 33 per cent. capacity. As production sagged below 20 per cent. at the middle of July, the present rate shows a substantial recovery.

Steel prices are moving both ways. This would look as if present prices are nearly if not quite at the bottom. Advances have been made on items as announced last week, while reductions here now taken place in tubular goods.

According to Pittsburgh reports, the steel industry is marked for a further increase in unemployment, as stocks are liquidated and normal relations are restored. It would appear as if steel is moving back towards a normal relation to business generally.

Montreal Harbor is experiencing considerable congestion at present. Grain freight rates are chiefly responsible for this condition. In fact so great is the congestion that considerable quantities have been diverted to Quebec.

The railroad shops are doing a fair share of repair work, and are buying small tool supplies from time to time. Small jobbing shops are also receiving a good amount of general business.

Several lines in the Toronto market show a reduction, and there is a rumor that some Canadian made machine tools are coming down in price. The latter statement is not verified however.

Small tools are still moving at a steady rate. Purchasers however buy only what they actually require, so that while business is steady, it is not for very large amounts.

The scrap situation is the same as last week, and it looks as if no change will take place for some time. Nobody seems to want to buy, even the dealers, who are sitting back calmly waiting for results.

The British Air Ministry are offering prizes for designers and inventors who submit specimens of safety tanks for fuel in aircraft. These prizes will reach as high as 2,000 pounds, and all entries have to reach the air ministry not later than Nov. 7th. The tanks will have to be ready for test by Dec. 1st.

TORONTO MARKET SHOWS IMPROVEMENT

TORONTO, Sept. 22nd.—It doesn't require a man with an optimistic nature to report better business conditions these days. Some little time ago, when you asked a dealer how business was he would generally say: Business, what's that?" But now his answer is entirely different. He will perk right up when you ask him the same question and say smilingly: "Oh, we can't complain at all. Business is rather better this week," etc. In other words, there is a feeling of confidence which was badly needed in the market. Not only is business better, but everybody seems to feel it will still further improve as time goes on.

"People have got tired waiting for still lower prices which cannot come," said one dealer. "They forgot for a time," he continued, "that we had actually lowered our prices, and were waiting on them to buy. It can't be expected that we can reach 1914 levels in all lines again, for our production costs are altogether different from those days."

Following this idea up, Canadian Machinery asked a dealer in machine tools and general supplies how present prices were in comparison with his 1914 figures. "I don't see that that would get us anywhere," was the reply, "because," continued this dealer, "our production and selling costs are altogether different from 1914. Take for example the following items: Our labor costs, the paper used for correspondence, packing, etc., the cloth bags; our rental, the packing cases and numerous other things entering into the cost of the product to be shipped have all gone up. Why then can people expect a 1914 price level? It's out of the question under present conditions."

A Novel Scheme.

Another machinery dealer told Canadian Machinery of a scheme which he would have very much liked to see put into effect some time ago when things were at their worst. In fact he suggested to one of the firms which he represents, that they try it out. However, for some reason or other the suggestion was not taken up, but viewed in the aftermath of events, the scheme is well worthy of consideration.

It was this dealer's idea to have the firm advertise broadcast the lowering of prices to the 1914 level. This naturally was a risky thing to do on the face of it considering the fact that such a price would never cover the actual cost of production. The scheme went further than that however. After two or three weeks, it was proposed to have the same firm announce that they found it impossible to sell their product at this low figure, therefore were forced to raise their prices 15 to 20 per cent., but that orders would be taken for a period of 30 days at the old figure.

The next month a similar announcement of further increase would appear

and so on until the price had reached where it should actually have been in the first place. In other words educate the buyer that machine tools cannot be made for a mere nothing. Those of course, who bought at the lowest figure would be the ones who would benefit, but it is very unlikely that many would have bought at rock bottom, for it is human nature to wait until the upgrade in any commodity has started before buying commences. However the scheme was not tried out, but we cannot help but wish we had seen the result of such an action.

Speaking to another machine tool dealer on the value of the Toronto exhibition as an order getter, this particular dealer stated that he believed he had received good results from his efforts to please at the exhibition. "Many of the prospects I met," he said, "were men I could not reach in any other way." While no actual orders resulted, the prospect of business in itself was well worth while.

Taking the machine tool trade as a whole, this week's business can be said to be very good. Enquiries are coming in every day and many of these look like real orders. The railroads have started to buy a few odds and ends, and this business is expected to increase very shortly. The Durant Car Co. coming to Toronto has caused considerable activity among dealers. At present it looks as if this new company will be an assembling proposition only but even then some equipment will be required.

In the supply business there have been some reductions, these including several lines of pipe, fittings, steam gauges, pressure gauges, a few valves, etc. The Yale and Towne Mfg. Co. have announced a reduction in their lines, and there is a rumor to the effect that Canadian-made lathes are due for a drop. A peculiar point has come to our attention regarding the price of torches. Some time ago the price of these came down to 1914 levels, then gradually they were boosted until now they are sold at the same figure as they were at previous to their drop. Almost sounds like the machine tool dealer's idea adapted to torches?

The Steel Market.

Seasonable improvement in the steel market continues. Sheets are moving quickly, also structural material of all kinds. Reinforcement material is especially active. Prices remain very much the same in all lines, and buyers seem to be more ready to close business.

Small tools are plodding along in steady fashion. Dealers in these lines are not worrying. Business is good considering general conditions, so that they are content to pick up what they can get. One dealer reports that while he was on the road he found that everybody he met was sure business was on the royal road to recovery.

The only branch of the market that needs to hold its head down this week is the scrap market. Consumers are right out of the market and dealers refuse to sell at lower prices, or to stock up any further. Asked if things looked better for next week, one dealer said that one was between the devil and the deep sea so far as the scrap situation was concerned. "To my mind," he concluded, "things are going to be dull for some time yet." The market from every angle but the latter looks good however, and there is every reason to feel confident that things are on the upgrade.

MONTREAL HARBOR IS CONGESTED RAILROAD SHOPS DOING REPAIR WORK

Special to CANADIAN MACHINERY.

MONTREAL.—For the past few weeks there has been a distinct improvement in general business conditions throughout the province, which fact seems to conform the statement that has been so often quoted, namely, "that the corner has been turned" and that we are at last on the upgrade. The week just passed has brought in some satisfactory reports. The fact that some of this business was seasonable trade, and only of a temporary nature, however, cannot be denied, but at the same time a large proportion of the business improvement reported is of a staple and permanent nature. The movement of supplies for heating plants, sheets for stove pipes and range boilers, etc., are all enjoying a largely increased business during the last few weeks.

Shipping along the water front of this city has been particularly active and the present congestion in the harbor is greater than anything that has ever been experienced before. This condition is a result of freight rates on grain for export via Montreal from the American ports of Duluth and Chicago, being cheaper than via Buffalo and New York and a large quantity of American grain is passing through Montreal, and this added to the regular shipments of Canadian grain has created the congestion. In fact considerable quantities of this grain have been diverted to Quebec to relieve the situation there. All the local elevators are working to capacity night and day and the old floating elevators, idle for ten years or more, have been pressed into service. The local press reports that the Harbor Commissioners are seriously contemplating extending their operations to the South Shore and erecting grain elevators at Longueuil.

The railway shops are doing a fair share of repair work and although buying no new equipment are in the market for small tool supplies from time to time. Small jobbing shops seem to be enjoying their fair share of trade. The larger shops have been actively engaged in looking up orders and they seem to have been successful in gathering in a number of small orders, but the large ones are conspicuous by their absence. This situation, however, enables these shops to keep their plants in operation and their organizations more or less intact.

Building seems to be going on in a comparatively satisfactory manner, and plans for next year's business indicate a greater activity than has been seen locally for a number of years.

The only quarter where steel seems to be moving in any quantities is in sheets and plates. The usual large demand for stove pipes is creating a demand for sheets. In addition there has been quite a large call for the heavy type of sheets also some light plates. There has been an increasing demand for range boilers and many large industrial concerns have been making steel drums and containers, replacing the older wooden types for oils, greases and similar lines. This has all resulted in quite a movement of this class of material.

There is practically no call for bars, and jobbers are not attempting to replace stock that has been exhausted. Thus many orders have to be sent on to the mills for fulfillment. The price of steel has nothing to do with this action on their part. There just appears to be no outlook for conditions in this line to improve and it would not seem to be good business policy to tie up money in a line that is not moving and does not promise to do so within a reasonable time.

Rails and rail bonds are being produced in limited quantities. There will be a nominal amount of this business all through the next year as most Canadian roads have deferred many maintenance jobs and feel that such work must receive immediate attention.

Structural shapes are very quiet. The only orders coming through are still for stock replacement purposes, and now and then for a small construction job.

Pig Iron.

The pig iron trade seems to continue in its gradual trend towards improvement. After the slight strengthening price from time to time in the last few weeks, it has evidently reached a point where it has decided to remain for a while, as there has been no change for ten days. The present price is only about that of production cost and as soon as the demand increases there will doubtless be a further increase in price. No one seems able to predict when anything approaching normal consumption will take place and until then no settled or staple price can be assured. A large percentage of the furnaces are idle and will not "blow in" until more attractive prices and a larger volume of business is offering.

Machine Tools.

Prices of machine tools are considered too high by the user and no sales have been reported for some time. There appears to be some attempts at reduction from some quarters. During the war all manufacturers increased the

capacity of their plants and in many cases the equipment they installed was not the best suited to their requirements but as delivery had to be made, this type of machinery had to be pressed into service. This did not tend to reduce costs and together with the high labor costs, machine tool prices soared. Reductions that seem reasonable have not yet been made, but to-day there is a general tendency toward more or less substantial reductions. Machine tool manufacturers are also getting rid of this surplus equipment that was not the most economical for them. Thus to-day there is a large quantity of second hand and rebuilt machinery for sale at relatively low prices. These tools are moving almost to the exclusion of the new tools. Manufacturers are also devoting themselves, during the quiet period, to the improvement of their products, and from time to time in the near future we can look for announcements of new tools having some very marked improvements, and many labor saving devices. These features with the inevitable increase in business will bring the users of machine tools into the market. Meanwhile business remains very quiet with only small sales being reported.

The sale of small tools and supplies still continues to be of the hand to mouth variety. A certain small volume seems to pass every week. Prices are unstable as liquidation by some firms and dealers has not yet been completed. Manufacturers are trying hard to get their lines in the hands of the jobbers with only fair success.

Little or no non-ferrous metal business is moving and the prices have remained unchanged. There is little or no promise of any immediate improvement in these lines.

The scrap metal market shows no improvement. Business is moving slowly and the prices are very weak.

FRANCE WANTS CANADIAN TRAIN

Opportunity is Afforded Canada to Send a Train to France for Exhibition Purposes. Special Privileges will be Afforded any Such Train

The French exhibition train has visited, and left Toronto. Without question it created deep interest. In fact one was lucky to get near the train, far less pass through it, so dense were the crowds. Our department of trade and commerce, and our Canadian railways are assisting in every possible way to make the tour a success, the latter handling the train free of charge.

As a complement to the French train exhibit, it is expected by the French goverment and greatly desired by the department of trade and commerce that a similar train containing Canadian exhibits will next year make a tour through France for the purpose of presenting to the French buyers, in an attractive and practical way, the resources of the Dominion. In turn the French government offers:—

1—The free transportation of the Canadian sample goods both ways across the ocean. 2.—The free warehousing of the Canadian sample goods in the docks of the French port selected. 3.—The gratuitous use of the railways and other equipment required for a complete exhibition train and its circulation throughout the principal cities of France. 4.—The use of the best theatres in practically every city visited by the Canadian train with the net proceeds of the entrance receipts for theatrical displays of films and other devices demonstrating the natural resuorces, industrial development, and natural beauties of Canada. 5.—The free use for a period of six months of the most suitable building in the city of Paris, presumably Le Petit Palais in Les Champs Elysees, for a fixed exhibition of the Canadian sample goods.

Speaking on the offer, the department of trade and commerce says that there appears to them no better method of instilling a greater knowledge and intimate appreciation by the French and Canadian peoples of their respective capabilities, than an exchange of commodities. The privileges granted by the French government are an exact replica of those which Canada has granted to the French exhibition train, but it must not be overlooked remarks the trade and commerce dept., that in such an exchange of facilities Canada will be the more largely benefited.

Canada will have an opportunity to advertise its resources to a market of 38,000,000 people, whereas in return, France will appeal to a market of less than 9,000,000 people. In addition, Canada will have the advantage of having an exhibit for an extended time in one of the most beautiful buildings in the world, where it would be viewed not only by the large population in Paris, (2,850,000.) but by the great travelling public, tourists and buyers who congregate in the French capital from all over the world.

Concluding their above remarks the dept. of trade and commerce say that they will be glad to take up the responsibility of the initial work in connection with any permanent organization to be formed later, and they also state that they will be pleased to receive suggestions and opinions from anyone interested. Such communications should be addressed to the Deputy Minister, Dept., Trade and Commerce, Ottawa.

The Hotel Mossop, Toronto, are going to build an addition to their present structure which will cost around $750,000. It is expected that the new portion will be completed around June or July next year, and this will mean that 140 more rooms, with a bath to each room will be available.

COMPETITION NOT WORRYING STEEL MEN

Believe That Competition Cannot Harm Them Much—Expect That Demand Will Increase Shortly

While American manufacturers of steel products admit that Germany and Belgium are showing activity in the export field, they nevertheless express complacency as to their own future. They base their reasons on the following points:—

1. The decreased activity by these countries during recent weeks. 2.—The demand by German workmen for a higher wage scale. 3.—The oversold condition of the German and Belgian markets making prompt delivery uncertain, and 4.—The betterment in the American situation indicated by a decline in prices here because of lower production costs and reduced freight rates for shipments to coast ports.

It is estimated that to keep American steel mills running at capacity 20 per cent of the output must be shipped abroad. The proportion applies at times when conditions at present are so far below the usual levels that to keep busy the full quota of steel workers and machinery today the exports would have to be something like 70 per cent of production.

As a matter of fact, continues a New York report, the average rate of output to capacity is estimated at less than 30 per cent., and of this the foreign shipments of raw steel material represent considerably less than 5 per cent. Export trade in steel has been particularly hard hit by the present world wide depression and its decline has been proportionately much greater than of domestic business.

The reasons for this are first, because the foreign markets, like our own, are suffering from overproduction and overloading, and from a consequent rapid decline of values. Time alone can work off the surplus.

But there must always be at least some demand, and for the few business opportunities offering in South America, Japan, China, India, Africa and the Dutch East Indies and other countries, there has developed a keen and unequal competition between the principal steel producing nations, which include the United States, Great Britain, Belgium, Germany and France, Great Britain, by reason of her coal strikes, has been almost out of the reckoning, and is only beginning to prepare for export trade. The most aggressive competitors of the United States are Germany and Belgium, neither of them comparable with America in point of out-turn, but amply able in quiet times like the present to provide the world, outside of the United States with its comparatively small requirements.

BELTING—No. 1 OAK TANNED

Extra heavy, single and double	15%
Standard	15 and 10%
Cut leather lacing, No. 1	2 00
Leather in side	2 40 3 00

TAPES

Chesterman Metallic, 50 ft.	$2 00
Lufkin Metallic, 603, 50 ft.	2 00
Admiral Steel Tape, 50 ft.	2 75
Admiral Steel Tape, 100 ft.	4 45
Major Jun. Steel Tape, 50 ft.	3 50
Rival Steel Tape, 50 ft.	2 75
Rival Steel Tape, 100 ft.	4 45
Reliable Jun. Steel Tape, 50 ft.	3 50

PLATING SUPPLIES

Polishing wheels, felt	$4 50
Polishing wheels, bull-neck	2 00
Emery in kegs, Turkish	8¾
Pumice, ground	06
Emery glue	30
Tripoli composition	9½
Crocus composition	12
Emery composition	11
Rouge, silver	64
Rouge, powder, nickel	38

Prices per lb.

ARTIFICIAL CORUNDUM

Grits, 6 to 70 inclusive	8½
Grits, 80 and finer	6

BRASS—Warehouse Price

Brass rods, base ½ in. to 1 in. rod	30
Brass sheets, 24 gauge and heavier, base	38
Brass tubing, seamless	42
Copper tubing, seamless	44

XXX Extra	21	Atlas	19
Peerless	22	X Empire	15
Grand	21½	Ideal	18
Superior	21½	X Press	13½
X L C R	16½		

Colored

Nickel ammonium sulphate	16½
Nickel carbonate	.30
Nickel sulphate	.17½
Potassium sulphide (substitute)	.40
Silver Chloride (per oz.)	1.15
Silver nitrate (per oz.)	1.10
Sodium bisulphate	.13
Sodium carbonate crystals	.04
Sodium cyanide, 127-130%	.39
Sodium hyposulphite per 100 lb.	6.50
Sodium phosphate	.15
Tin chloride	.80
Zinc chloride, C.P.	.30
Zinc sulphate	.08

Prices per lb. unless otherwise stated

200 Caps per Hour
With a Geometric Self-Opening Die Head

Threading Aluminum Ford Radiator Caps 2" - 16 U. S. F., 5/8" Long

The Foreman of a Machine Shop was recently asked why he used Geometric Die Heads in preference to any others.

The Foreman replied that he HAD to use Geometric Die Heads because they were the ONLY ONES HE COULD FIND THAT WOULD CUT A STRAIGHT AND CLOSE ENOUGH THREAD FOR THEIR WORK.

It is such facts as that which leave the Geometrics without a rival.

PUMPING STATION FOR MONTREAL WILL BE MODERN IN EVERY RESPECT

MONTREAL is growing. In fact is growing so rapidly that its present water supply service has to be increased again. As the city has grown, additions to the water supply have been made, but during the last year the water consumption increased two million gallons per day. The capacity of the Point St. Charles low level pumping station has been increased several times, but the later additions include electric driven turbine pumps. In the old pumping station are three of these units. There are two units each of thirty million gallons per day capacity, and one of twenty millions. One of the larger is a De Laval pump, and the other a Worthington. Both are driven by Westinghouse motors. The smaller pump is a Mather and Platt, driven by a Canadian General Electric motor.

Together these pumps have a daily capacity of eighty million gallons. During the hours of peak load however, they cannot take care of the city's requirements, and steam units are thus daily called into service. After due consideration it was decided to build a new pumping station as the old one had been enlarged to a point where it was neither practical nor advisable to go farther.

The new station is located a short distance from the old station, and very close to the filtration plant. The water is taken from the St. Lawrence River at a point some distance up the river and is conveyed to the pumping station by means of an aqueduct. Almost twenty-five feet of lead is obtained and some three thousand horse power can be developed, if desired, from the water passing through the aqueduct without increasing the velocity beyond that which is necessary to carry away any sediment and thus prevent the gradual filling up of the aqueduct. The present lining of the banks is designed for water supply only and not for power purposes. At present all water passes through the filtration plant and experiments have been conducted, the results of which, lead the engineers of the Montreal Water Board to believe that the capacity of the filtration plant can be so increased that the requirements of the city can be taken care of for several years to come.

The new station is to be the best equipped and most elaborate of its kind in Canada and one of the most complete on the continent. It will have a capacity of three hundred million gallons per day, divided in two similar wings, each having a capacity of one hundred and fifty million gallons per day and situated symmetrically about a central control portion of the building. It is only proposed to build one wing and the central control section of the building at this time. The wing will contain six pumping units of thirty million gallons capacity a day. As one unit will be always held ready as a spare the nominal capacity will thus be one hundred and fifty million gallons per day.

The building will contain its own machine shop, the executive offices of the Montreal Water Board, and one section will contain the transformers, oil switches, etc. The feature however, is the central control. One man will be able to operate and control every unit in the station. Besides, the operator will be so advantageously located that he can see every part of the room where the motors and pumps are located. In addition a very complete signalling system is installed, similar to the marine telegraph used by ship's officers on the bridge of a vessel to communicate with the staff in the engine room. The feature of this, is that every order is confirmed by the man receiving it before it is executed.

Rarely has it been the privilege of the writer to see an installation where greater care and thought have been exercised to prevent a breakdown from either electrical or mechanical failures. The electricity is received from the power company in two towers each quite separate from the other and both distinctly apart from the pumping station building. Here lightning arrestors and other protective apparatus are found. Several separate underground lines lead from the towers to the transformers. All equipment is of generous proportions and amply protected. Throughout, duplicate installations of leads, switches, etc., are found, and where there is any chance of even a temporary tie up, triplicate and quadruplicate installations are made. No risk from hot contacts in switches are taken. All equipment is spaced well apart so that a "short" or fire in one piece of equipment will not in any way jeopardize another. Mr. Chas. Des Baillets of the Montreal Water Board had charge of the design of the building, and the selection of equipment. Great credit is due him for the precautionary measures he has taken to prevent a breakdown in the equipment.
